```

Description

Plots regression terms against their predictors, optionally with standard errors and partial residuals added.

Usage

```
termplot(model, data = NULL, envir = environment(formula(model)),
  partial.resid = FALSE, rug = FALSE,
  terms = NULL, se = FALSE,
  xlabs = NULL, ylabs = NULL, main = NULL,
  col.term = 2, lwd.term = 1.5,
  col.se = "orange", lty.se = 2, lwd.se = 1,
  col.res = "gray", cex = 1, pch = par("pch"),
  col.smth = "darkred", lty.smth = 2, span.smth = 2/3,
  ask = dev.interactive() && nb.fig < n.tms,
  use.factor.levels = TRUE, smooth = NULL, ylim = "common",
  plot = TRUE, transform.x = FALSE, ...)
```

Arguments

| | |
|-----------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>model</code> | fitted model object |
| <code>data</code> | data frame in which variables in <code>model</code> can be found |
| <code>envir</code> | environment in which variables in <code>model</code> can be found |
| <code>partial.resid</code> | logical; should partial residuals be plotted? |
| <code>rug</code> | add rugplots (jittered 1-d histograms) to the axes? |
| <code>terms</code> | which terms to plot (default <code>NULL</code> means all terms); a vector passed to predict (<code>..</code> , <code>type = "terms"</code> , <code>terms = *</code>). |
| <code>se</code> | plot pointwise standard errors? |
| <code>xlabs</code> | vector of labels for the x axes |
| <code>ylabs</code> | vector of labels for the y axes |
| <code>main</code> | logical, or vector of main titles; if <code>TRUE</code> , the model's call is taken as main title, <code>NULL</code> or <code>FALSE</code> mean no titles. |
| <code>col.term</code> , <code>lwd.term</code> | color and line width for the 'term curve', see lines . |
| <code>col.se</code> , <code>lty.se</code> , <code>lwd.se</code> | color, line type and line width for the 'twice-standard-error curve' when <code>se = TRUE</code> . |
| <code>col.res</code> , <code>cex</code> , <code>pch</code> | color, plotting character expansion and type for partial residuals, when <code>partial.resid = TRUE</code> , see points . |
| <code>ask</code> | logical; if <code>TRUE</code> , the user is <i>asked</i> before each plot, see par (<code>ask=.</code>). |
| <code>use.factor.levels</code> | Should x-axis ticks use factor levels or numbers for factor terms? |
| <code>smooth</code> | <code>NULL</code> or a function with the same arguments as panel.smooth to draw a smooth through the partial residuals for non-factor terms |

| | |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| lty.smth, col.smth, span.smth | Passed to smooth |
| ylim | an optional range for the y axis, or "common" when a range sufficient for all the plot will be computed, or "free" when limits are computed for each plot. |
| plot | if set to FALSE plots are not produced: instead a list is returned containing the data that would have been plotted. |
| transform.x | logical vector; if an element (recycled as necessary) is TRUE, partial residuals for the corresponding term are plotted against transformed values. The model response is then a straight line, allowing a ready comparison against the data or against the curve obtained from smooth-panel.smooth. |
| ... | other graphical parameters. |

Details

The model object must have a predict method that accepts type = "terms", e.g., `glm` in the **stats** package, `coxph` and `survreg` in the **survival** package.

For the partial.resid = TRUE option model must have a `residuals` method that accepts type = "partial", which `lm` and `glm` do.

The data argument should rarely be needed, but in some cases termplot may be unable to reconstruct the original data frame. Using na.action=na.exclude makes these problems less likely.

Nothing sensible happens for interaction terms, and they may cause errors.

The plot = FALSE option is useful when some special action is needed, e.g. to overlay the results of two different models or to plot confidence bands.

Value

For plot = FALSE, a list with one element for each plot which would have been produced. Each element of the list is a data frame with variables x, y, and optionally the pointwise standard errors se. For continuous predictors x will contain the ordered unique values and for a factor it will be a factor containing one instance of each level. The list has attribute "constant" copied from the predicted terms object.

Otherwise, the number of terms, invisibly.

See Also

For (generalized) linear models, `plot.lm` and `predict.glm`.

Examples

```
require(graphics)

had.splines <- "package:splines" %in% search()
if(!had.splines) rs <- require(splines)
x <- 1:100
z <- factor(rep(LETTERS[1:4], 25))
y <- rnorm(100, sin(x/10)+as.numeric(z))
model <- glm(y ~ ns(x, 6) + z)
```

```

par(mfrow = c(2,2)) ## 2 x 2 plots for same model :
termplot(model, main = paste("termplot( ", deparse(model$call)," ...))")
termplot(model, rug = TRUE)
termplot(model, partial.resid = TRUE, se = TRUE, main = TRUE)
termplot(model, partial.resid = TRUE, smooth = panel.smooth, span.smth = 1/4)
if(!had.splines && rs) detach("package:splines")

if(requireNamespace("MASS", quietly = TRUE)) {
  hills.lm <- lm(log(time) ~ log(climb)+log(dist), data = MASS:hills)
  termplot(hills.lm, partial.resid = TRUE, smooth = panel.smooth,
           terms = "log(dist)", main = "Original")
  termplot(hills.lm, transform.x = TRUE,
           partial.resid = TRUE, smooth = panel.smooth,
           terms = "log(dist)", main = "Transformed")
}

```

terms

Model Terms

Description

The function `terms` is a generic function which can be used to extract *terms* objects from various kinds of R data objects.

Usage

```
terms(x, ...)
```

Arguments

| | |
|------------------|----------------------------------------------------|
| <code>x</code> | object used to select a method to dispatch. |
| <code>...</code> | further arguments passed to or from other methods. |

Details

There are methods for classes `"aovlist"`, and `"terms"` `"formula"` (see [terms.formula](#)): the default method just extracts the `terms` component of the object, or failing that a `"terms"` attribute (as used by [model.frame](#)).

There are [print](#) and [labels](#) methods for class `"terms"`: the latter prints the term labels (see [terms.object](#)).

Value

An object of class `c("terms", "formula")` which contains the *terms* representation of a symbolic model. See [terms.object](#) for its structure.

References

Chambers, J. M. and Hastie, T. J. (1992) *Statistical models*. Chapter 2 of *Statistical Models in S* eds J. M. Chambers and T. J. Hastie, Wadsworth & Brooks/Cole.

[terms.object](#), [terms.formula](#), [lm](#), [glm](#), [formula](#).

terms.formula

Construct a terms Object from a Formula

Description

This function takes a formula and some optional arguments and constructs a terms object. The terms object can then be used to construct a [model.matrix](#).

Usage

```
## S3 method for class 'formula'
terms(x, specials = NULL, abb = NULL, data = NULL, neg.out = TRUE,
      keep.order = FALSE, simplify = FALSE, ...,
      allowDotAsName = FALSE)
```

Arguments

| | |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x | a formula . |
| specials | which functions in the formula should be marked as special in the terms object? A character vector or NULL. |
| abb | Not implemented in R; deprecated. |
| data | a data frame from which the meaning of the special symbol . can be inferred. It is used only if there is a . in the formula. |
| neg.out | Not implemented in R; deprecated. |
| keep.order | a logical value indicating whether the terms should keep their positions. By default, when FALSE, the terms are reordered so that main effects come first, followed by the interactions, all second-order, all third-order and so on. Effects of a given order are kept in the order specified. |
| simplify | should the formula be expanded and simplified, the pre-1.7.0 behaviour? |
| ... | further arguments passed to or from other methods. |
| allowDotAsName | normally . in a formula refers to the remaining variables contained in data. Exceptionally, . can be treated as a name for non-standard uses of formulae. |

Details

Not all of the options work in the same way that they do in S and not all are implemented.

Value

A terms object is returned. It is the re-ordered formula (unless `keep.order = TRUE`) with several [attributes](#), see [terms.object](#) for details. In all cases variables within an interaction term in the formula are re-ordered by the ordering of the "variables" attribute, which is the order in which the variables occur in the formula.

See Also

[terms](#), [terms.object](#), also for examples.

| | |
|--------------|-------------------------------------|
| terms.object | <i>Description of Terms Objects</i> |
|--------------|-------------------------------------|

Description

An object of class [terms](#) holds information about a model. Usually the model was specified in terms of a [formula](#) and that formula was used to determine the terms object.

Details

The object itself is simply the result of `terms.formula(<formula>)`. It has a number of attributes and they are used to construct the model frame:

factors An integer matrix of variables by terms showing which variables appear in which terms. The entries are

- 0** if the variable does not occur in the term,
- 1** if it does occur and should be coded by contrasts, and
- 2** if it occurs and should be coded via dummy variables for all levels (as when a lower-order term is missing).

Note that variables in main effects always receive 1, even if the intercept is missing (in which case the first one should be coded with dummy variables). If there are no terms other than an intercept and offsets, this is `integer(0)`.

term.labels A character vector containing the labels for each of the terms in the model, except for offsets. Note that these are after possible re-ordering of terms.

Non-syntactic names will be quoted by backticks: this makes it easier to re-construct the formula from the term labels.

variables A call to `list` of the variables in the model.

intercept Either 0, indicating no intercept is to be fit, or 1 indicating that an intercept is to be fit.

order A vector of the same length as `term.labels` indicating the order of interaction for each term.

response The index of the variable (in `variables`) of the response (the left hand side of the formula). Zero, if there is no response.

offset If the model contains `offset` terms there is an `offset` attribute indicating which variable(s) are offsets

specials If a **specials** argument was given to [terms.formula](#) there is a **specials** attribute, a pairlist of vectors (one for each specified special function) giving numeric indices of the arguments of the list returned as the **variables** attribute which contain these special functions.

dataClasses optional. A named character vector giving the classes (as given by [.MFclass](#)) of the variables used in a fit.

predvars optional. An expression to help in computing predictions at new covariate values; see [makepredictcall](#).

The object has class `c("terms", "formula")`.

Note

These objects are different from those found in S. In particular there is no **formula** attribute: instead the object is itself a formula. (Thus, the mode of a **terms** object is different.)

Examples of the **specials** argument can be seen in the [aov](#) and [coxph](#) functions, the latter from package **survival**.

See Also

[terms](#), [formula](#).

Examples

```
## use of specials (as used for gam() in packages mgcv and gam)
(tf <- terms(y ~ x + x:z + s(x), specials = "s"))
## Note that the "factors" attribute has variables as row names
## and term labels as column names, both as character vectors.
attr(tf, "specials")    # index 's' variable(s)
rownames(attr(tf, "factors"))[attr(tf, "specials")]$s]

## we can keep the order by
terms(y ~ x + x:z + s(x), specials = "s", keep.order = TRUE)
```

time

Sampling Times of Time Series

Description

time creates the vector of times at which a time series was sampled.

cycle gives the positions in the cycle of each observation.

frequency returns the number of samples per unit time and **deltat** the time interval between observations (see [ts](#)).

Usage

```
time(x, ...)
## Default S3 method:
time(x, offset = 0, ts.eps = getOption("ts.eps"), ...)

cycle(x, ...)
frequency(x, ...)
deltat(x, ...)
```

Arguments

| | |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code> | a univariate or multivariate time-series, or a vector or matrix. |
| <code>offset</code> | can be used to indicate when sampling took place in the time unit. 0 (the default) indicates the start of the unit, 0.5 the middle and 1 the end of the interval. |
| <code>ts.eps</code> | time series comparison tolerance, used in <code>time()</code> to determine if values close than <code>ts.eps</code> to an integer should be <code>round()</code> ed to it in order to preserve the “year”. |
| <code>...</code> | extra arguments for future methods. |

Details

These are all generic functions, which will use the `tsp` attribute of `x` if it exists. `time` and `cycle` have methods for class `ts` that coerce the result to that class.

`time()` `round()`s values close to an integer, i.e., closer than `ts.eps`, since R 4.3.0. For previous behaviour, you can call it with `ts.eps = 0`.

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

`ts`, `start`, `tsp`, `window`.
`date` for clock time, `system.time` for CPU usage.

Examples

```
require(graphics)

cycle(presidents)
# a simple series plot
plot(as.vector(time(presidents)), as.vector(presidents), type = "l")
```

toeplitz

*Create Symmetric and Asymmetric Toeplitz Matrix***Description**

In its simplest use, `toeplitz()` forms a symmetric Toeplitz matrix given its first column (or row). For the general case, asymmetric and non-square Toeplitz matrices are formed either by specifying the first column and row separately,

```
T1 <- toeplitz(col, row)
```

or by

```
T <- toeplitz2(x, nr, nc)
```

where only one of (nr, nc) needs to be specified. In the latter case, the simple equivalence $T_{i,j} = x_{i-j+n_c}$ is fulfilled where $n_c = \text{ncol}(T)$.

Usage

```
toeplitz(x, r = NULL, symmetric = is.null(r))
toeplitz2(x, nrow = length(x) + 1 - ncol, ncol = length(x) + 1 - nrow)
```

Arguments

| | |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code> | for <code>toeplitz(x, *)</code> : the first column of the Toeplitz matrix; for <code>toeplitz2(x, *)</code> it is the upper-and-left border of the Toeplitz matrix, i.e., from top-right to bottom-left, such that $T[i, j] == x[i - j + \text{ncol}]$. |
| <code>r</code> | the first row of the target Toeplitz matrix; only needed in asymmetric cases. |
| <code>symmetric</code> | optional logical indicating if the matrix should be symmetric. |
| <code>nrow, ncol</code> | the number of rows and columns; only one needs to be specified. |

Value

The $n \times m$ Toeplitz matrix T ; for

`toeplitz()`: $\text{dim}(T)$ is (n, m) and $m == \text{length}(x)$ and $n == m$ in the symmetric case or $n == \text{length}(r)$ otherwise.

`toeplitz2()`: $\text{dim}(T) == c(\text{nrow}, \text{ncol})$.

Author(s)

A. Trapletti and Martin Maechler (speedup and asymmetric extensions)

Examples

```
x <- 1:5
toeplitz(x)

T. <- toeplitz(1:5, 11:13) # with a *Warning* x[1] != r[1]
T2 <- toeplitz2(c(13:12, 1:5), 5, 3) # this is the same matrix:
stopifnot(identical(T., T2))

# Matrix of character (could also have logical, raw, complex ..) {also warning}:
noquote(toeplitz(letters[1:4], LETTERS[20:26]))

## A convolution/smoothing weight matrix :
m <- 17
k <- length(wts <- c(76, 99, 60, 20, 1))
n <- m-k+1
## Convolution
W <- toeplitz2(c(rep(0, m-k), wts, rep(0, m-k)), ncol=n)

## "display" nicely :
if(requireNamespace("Matrix"))
  print(Matrix::Matrix(W)) else {
    colnames(W) <- paste0(" ", if(n <= 9) 1:n else c(1:9, letters[seq_len(n-9)]))
    print(W)
  }

## scale W to have column sums 1:
W. <- W / sum(wts)
all.equal(rep(1, ncol(W.)), colSums(W.), check.attributes = FALSE)
## Visualize "mass-preserving" convolution
x <- 1:n; f <- function(x) exp(-((x - .4*n)/3)^2)
y <- f(x) + rep_len(3:-2, n)/10
## Smoothing convolution:
y.hat <- W. %*% y # y.hat := smoothed(y) ("mass preserving" -> longer than y)
stopifnot(length(y.hat) == m, m == n + (k-1))
plot(x, y, type="b", xlim=c(1,m)); curve(f(x), 1,n, col="gray", lty=2, add=TRUE)
lines(1:m, y.hat, col=2, lwd=3)
rbind(sum(y), sum(y.hat)) ## mass preserved

## And, yes, convolve(y, *) does the same when called appropriately:
all.equal(c(y.hat, convolve(y, rev(wts/sum(wts))), type="open"))
```

Description

The function `ts` is used to create time-series objects.

`as.ts` and `is.ts` coerce an object to a time-series and test whether an object is a time series.

Usage

```

ts(data = NA, start = 1, end = numeric(), frequency = 1,
   deltat = 1, ts.eps = getOption("ts.eps"),
   class = if(nseries > 1) c("mts", "ts", "matrix", "array") else "ts",
   names = )
as.ts(x, ...)
is.ts(x)

is.mts(x)

```

Arguments

| | |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>data</code> | a vector or matrix of the observed time-series values. A data frame will be coerced to a numeric matrix via <code>data.matrix</code> . (See also ‘Details’.) |
| <code>start</code> | the time of the first observation. Either a single number or a vector of two numbers (the second of which is an integer), which specify a natural time unit and a (1-based) number of samples into the time unit. See the examples for the use of the second form. |
| <code>end</code> | the time of the last observation, specified in the same way as <code>start</code> . |
| <code>frequency</code> | the number of observations per unit of time. |
| <code>deltat</code> | the fraction of the sampling period between successive observations; e.g., 1/12 for monthly data. Only one of <code>frequency</code> or <code>deltat</code> should be provided. |
| <code>ts.eps</code> | time series comparison tolerance. Frequencies are considered equal if their absolute difference is less than <code>ts.eps</code> . |
| <code>class</code> | class to be given to the result, or none if NULL or "none". The default is "ts" for a single series, or <code>c("mts", "ts", "matrix", "array")</code> for multiple series. |
| <code>names</code> | a character vector of names for the series in a multiple series: defaults to the colnames of <code>data</code> , or "Series 1", "Series 2", |
| <code>x</code> | an arbitrary R object. |
| <code>...</code> | arguments passed to methods (unused for the default method). |

Details

The function `ts` is used to create time-series objects. These are vectors or matrices which inherit from class "ts" (and have additional attributes) which represent data which has been sampled at equispaced points in time. In the matrix case, each column of the matrix data is assumed to contain a single (univariate) time series. Time series must have at least one observation, and although they need not be numeric there is very limited support for non-numeric series.

Class "ts" has a number of methods. In particular arithmetic will attempt to align time axes, and subsetting to extract subsets of series can be used (e.g., `EuStockMarkets[, "DAX"]`). However, subsetting the first (or only) dimension will return a matrix or vector, as will matrix subsetting. Subassignment can be used to replace values but not to extend a series (see [window](#)). There is a method for `t` that transposes the series as a matrix (a one-column matrix if a vector) and hence returns a result that does not inherit from class "ts".

Argument `frequency` indicates the sampling frequency of the time series, with the default value 1 indicating one sample in each unit time interval. For example, one could use a value of 7 for frequency when the data are sampled daily, and the natural time period is a week, or 12 when the data are sampled monthly and the natural time period is a year. Values of 4 and 12 are assumed in (e.g.) `print` methods to imply a quarterly and monthly series respectively. `frequency` need not be a whole number: for example, `frequency = 0.2` would imply sampling once every five time units.

`as.ts` is generic. Its default method will use the `tsp` attribute of the object if it has one to set the start and end times and frequency.

`is.ts()` tests if an object is a time series, i.e., inherits from `"ts"` and is of positive length.

`is.mts(x)` tests if an object `x` is a multivariate time series, i.e., fulfills `is.ts(x)`, `is.matrix(x)` and inherits from class `"mts"`.

`tsp`, `frequency`, `start`, `end`, `time`, `window`; `print.ts`, the print method for time series objects; `plot.ts`, the plot method for time series objects.

For other definitions of 'time series' (e.g., time-ordered observations) see the CRAN task view at <https://CRAN.R-project.org/view=TimeSeries>.

Examples

```
require(graphics)

ts(1:10, frequency = 4, start = c(1959, 2)) # 2nd Quarter of 1959
print( ts(1:10, frequency = 7, start = c(12, 2)), calendar = TRUE)
# print.ts(.)
## Using July 1954 as start date:
gnp <- ts(cumsum(1 + round(rnorm(100), 2)),
          start = c(1954, 7), frequency = 12)
plot(gnp) # using 'plot.ts' for time-series plot

## Multivariate
z <- ts(matrix(rnorm(300), 100, 3), start = c(1961, 1), frequency = 12)
class(z)
is.mts(z)
head(z) # as "matrix"
plot(z)
plot(z, plot.type = "single", lty = 1:3)

## A phase plot:
plot(nhtemp, lag(nhtemp, 1), cex = .8, col = "blue",
     main = "Lag plot of New Haven temperatures")
```

Description

Methods for objects of class "ts", typically the result of [ts](#).

Usage

```
## S3 method for class 'ts'
diff(x, lag = 1, differences = 1, ...)

## S3 method for class 'ts'
na.omit(object, ...)
```

Arguments

| | |
|-------------|------------------------------------------------------------------|
| x | an object of class "ts" containing the values to be differenced. |
| lag | an integer indicating which lag to use. |
| differences | an integer indicating the order of the difference. |
| object | a univariate or multivariate time series. |
| ... | further arguments to be passed to or from methods. |

Details

The `na.omit` method omits initial and final segments with missing values in one or more of the series. 'Internal' missing values will lead to failure.

Value

For the `na.omit` method, a time series without missing values. The class of object will be preserved.

See Also

[diff](#); [na.omit](#), [na.fail](#), [na.contiguous](#).

`ts.plot`*Plot Multiple Time Series*

Description

Plot several time series on a common plot. Unlike [plot.ts](#) the series can have a different time bases, but they should have the same frequency.

Usage

```
ts.plot(..., gpars = list())
```

Arguments

| | |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <code>...</code> | one or more univariate or multivariate time series. |
| <code>gpars</code> | list of named graphics parameters to be passed to the plotting functions. Those commonly used can be supplied directly in <code>...</code> |

Value

None.

Note

Although this can be used for a single time series, `plot` is easier to use and is preferred.

See Also

[plot.ts](#)

Examples

```
require(graphics)

ts.plot(ldeaths, mdeaths, fdeaths,
       gpars=list(xlab="year", ylab="deaths", lty=c(1:3)))
```

| | |
|----------|-------------------------------------|
| ts.union | <i>Bind Two or More Time Series</i> |
|----------|-------------------------------------|

Description

Bind time series which have a common frequency. `ts.union` pads with NAs to the total time coverage, `ts.intersect` restricts to the time covered by all the series.

Usage

```
ts.intersect(..., dframe = FALSE)
ts.union(..., dframe = FALSE)
```

Arguments

| | |
|---------------------|--------------------------------------------------------------------------------------------------|
| <code>...</code> | two or more univariate or multivariate time series, or objects which can coerced to time series. |
| <code>dframe</code> | logical; if TRUE return the result as a data frame. |

Details

As a special case, `...` can contain vectors or matrices of the same length as the combined time series of the time series present, as well as those of a single row.

Value

A time series object if `dframe` is FALSE, otherwise a data frame.

See Also

[cbind.](#)

Examples

```
ts.union(mdeaths, fdeaths)
cbind(mdeaths, fdeaths) # same as the previous line
ts.intersect(window(mdeaths, 1976), window(fdeaths, 1974, 1978))

sales1 <- ts.union(BJsales, lead = BJsales.lead)
ts.intersect(sales1, lead3 = lag(BJsales.lead, -3))
```

`tsdiag`*Diagnostic Plots for Time-Series Fits*

Description

A generic function to plot time-series diagnostics.

Usage

```
tsdiag(object, gof.lag, ...)
```

Arguments

| | |
|----------------------|-------------------------------------------------------------------|
| <code>object</code> | a fitted time-series model |
| <code>gof.lag</code> | the maximum number of lags for a Portmanteau goodness-of-fit test |
| <code>...</code> | further arguments to be passed to particular methods |

Details

This is a generic function. It will generally plot the residuals, often standardized, the autocorrelation function of the residuals, and the p-values of a Portmanteau test for all lags up to `gof.lag`.

The methods for [arima](#) and [StructTS](#) objects plots residuals scaled by the estimate of their (individual) variance, and use the Ljung–Box version of the portmanteau test.

Value

None. Diagnostics are plotted.

See Also

[arima](#), [StructTS](#), [Box.test](#)

Examples

```
require(graphics)

fit <- arima(lh, c(1,0,0))
tsdiag(fit)

## see also examples(arima)

(fit <- StructTS(log10(JohnsonJohnson), type = "BSM"))
tsdiag(fit)
```

tsp*Tsp Attribute of Time-Series-like Objects*

Description

tsp returns the tsp attribute (or NULL). It is included for compatibility with S version 2. `tsp<-` sets the tsp attribute. `hasTsp` ensures x has a tsp attribute, by adding one if needed.

Usage

```
tsp(x)
tsp(x) <- value
hasTsp(x)
```

Arguments

| | |
|-------|---------------------------------------------------------------|
| x | a vector or matrix or univariate or multivariate time-series. |
| value | a numeric vector of length 3 or NULL. |

Details

The tsp attribute gives the start time *in time units*, the end time and the frequency (the number of observations per unit of time, e.g. 12 for a monthly series).

Assignments are checked for consistency.

Assigning NULL which removes the tsp attribute *and* any "ts" (or "mts") class of x.

Value

An object which differs from x only in the tsp attribute (unless NULL is assigned).

`hasTsp` adds, if needed, an attribute with a start time and frequency of 1 and end time `NROW(x)`.

See Also

[ts](#), [time](#), [start](#).

tsSmooth*Use Fixed-Interval Smoothing on Time Series*

Description

Performs fixed-interval smoothing on a univariate time series via a state-space model. Fixed-interval smoothing gives the best estimate of the state at each time point based on the whole observed series.

Usage

```
tsSmooth(object, ...)
```

Arguments

| | |
|--------|-----------------------------------------------------------------------------------|
| object | a time-series fit. Currently only class " StructTS " is supported |
| ... | possible arguments for future methods. |

Value

A time series, with as many dimensions as the state space and results at each time point of the original series. (For seasonal models, only the current seasonal component is returned.)

Author(s)

B. D. Ripley

References

Durbin, J. and Koopman, S. J. (2001) *Time Series Analysis by State Space Methods*. Oxford University Press.

See Also

[KalmanSmooth](#), [StructTS](#).

For examples consult [AirPassengers](#), [JohnsonJohnson](#) and [Nile](#).

Description

Functions of the distribution of the studentized range, R/s , where R is the range of a standard normal sample and $df \times s^2$ is independently distributed as chi-squared with df degrees of freedom, see [pchisq](#).

Usage

```
ptukey(q, nmeans, df, nranges = 1, lower.tail = TRUE, log.p = FALSE)
qtukey(p, nmeans, df, nranges = 1, lower.tail = TRUE, log.p = FALSE)
```

Arguments

| | |
|-------------------------|---------------------------------------------------------------------------------------|
| <code>q</code> | vector of quantiles. |
| <code>p</code> | vector of probabilities. |
| <code>nmeans</code> | sample size for range (same for each group). |
| <code>df</code> | degrees of freedom for s (see below). |
| <code>nranges</code> | number of <i>groups</i> whose maximum range is considered. |
| <code>log.p</code> | logical; if TRUE, probabilities p are given as $\log(p)$. |
| <code>lower.tail</code> | logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$. |

Details

If $n_g = \text{nranges}$ is greater than one, R is the *maximum* of n_g groups of $n\text{means}$ observations each.

Value

`ptukey` gives the distribution function and `qtukey` its inverse, the quantile function.

The length of the result is the maximum of the lengths of the numerical arguments. The other numerical arguments are recycled to that length. Only the first elements of the logical arguments are used.

Note

A Legendre 16-point formula is used for the integral of `ptukey`. The computations are relatively expensive, especially for `qtukey` which uses a simple secant method for finding the inverse of `ptukey`. `qtukey` will be accurate to the 4th decimal place.

Source

`qtukey` is in part adapted from Odeh and Evans (1974).

Examples

```
if(interactive())
  curve(ptukey(x, nm = 6, df = 5), from = -1, to = 8, n = 101)
(p tt <- ptukey(0:10, 2, df = 5))
(q tt <- qtukey(.95, 2, df = 2:11))
## The precision may be not much more than about 8 digits:
summary(abs(.95 - ptukey(q tt, 2, df = 2:11)))
```

| | |
|----------|-----------------------------------------------------|
| TukeyHSD | <i>Compute Tukey Honest Significant Differences</i> |
|----------|-----------------------------------------------------|

Description

Create a set of confidence intervals on the differences between the means of the levels of a factor with the specified family-wise probability of coverage. The intervals are based on the Studentized range statistic, Tukey’s ‘Honest Significant Difference’ method.

Usage

```
TukeyHSD(x, which, ordered = FALSE, conf.level = 0.95, ...)
```

Arguments

| | |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x | A fitted model object, usually an aov fit. |
| which | A character vector listing terms in the fitted model for which the intervals should be calculated. Defaults to all the terms. |
| ordered | A logical value indicating if the levels of the factor should be ordered according to increasing average in the sample before taking differences. If ordered is true then the calculated differences in the means will all be positive. The significant differences will be those for which the lwr end point is positive. |
| conf.level | A numeric value between zero and one giving the family-wise confidence level to use. |
| ... | Optional additional arguments. None are used at present. |

Details

This is a generic function: the description here applies to the method for fits of class "aov".

When comparing the means for the levels of a factor in an analysis of variance, a simple comparison using t-tests will inflate the probability of declaring a significant difference when it is not in fact present. This because the intervals are calculated with a given coverage probability for each interval but the interpretation of the coverage is usually with respect to the entire family of intervals.

John Tukey introduced intervals based on the range of the sample means rather than the individual differences. The intervals returned by this function are based on this Studentized range statistics.

The intervals constructed in this way would only apply exactly to balanced designs where there are the same number of observations made at each level of the factor. This function incorporates an adjustment for sample size that produces sensible intervals for mildly unbalanced designs.

If which specifies non-factor terms these will be dropped with a warning: if no terms are left this is an error.

Value

A list of class `c("multicomp", "TukeyHSD")`, with one component for each term requested in which. Each component is a matrix with columns `diff` giving the difference in the observed means, `lwr` giving the lower end point of the interval, `upr` giving the upper end point and `p adj` giving the p-value after adjustment for the multiple comparisons.

There are print and plot methods for class "TukeyHSD". The plot method does not accept `xlab`, `ylab` or `main` arguments and creates its own values for each plot.

See Also

[aov](#), [qtukey](#), [model.tables](#), [glht](#) in package **multcomp**.

Examples

```
require(graphics)

summary(fm1 <- aov(breaks ~ wool + tension, data = warpbreaks))
TukeyHSD(fm1, "tension", ordered = TRUE)
plot(TukeyHSD(fm1, "tension"))
```

Description

These functions provide information about the uniform distribution on the interval from min to max. dunif gives the density, punif gives the distribution function qunif gives the quantile function and runif generates random deviates.

Usage

```
dunif(x, min = 0, max = 1, log = FALSE)
punif(q, min = 0, max = 1, lower.tail = TRUE, log.p = FALSE)
qunif(p, min = 0, max = 1, lower.tail = TRUE, log.p = FALSE)
runif(n, min = 0, max = 1)
```

Arguments

| | |
|------------|------------------------------------------------------------------------------------------|
| x, q | vector of quantiles. |
| p | vector of probabilities. |
| n | number of observations. If length(n) > 1, the length is taken to be the number required. |
| min, max | lower and upper limits of the distribution. Must be finite. |
| log, log.p | logical; if TRUE, probabilities p are given as log(p). |
| lower.tail | logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$. |

Details

If min or max are not specified they assume the default values of 0 and 1 respectively.

The uniform distribution has density

$$f(x) = \frac{1}{\max - \min}$$

for $\min \leq x \leq \max$.

For the case of $u := \min == \max$, the limit case of $X \equiv u$ is assumed, although there is no density in that case and dunif will return NaN (the error condition).

runif will not generate either of the extreme values unless max = min or max-min is small compared to min, and in particular not for the default arguments.

Value

dunif gives the density, punif gives the distribution function, qunif gives the quantile function, and runif generates random deviates.

The length of the result is determined by n for runif, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.

Note

The characteristics of output from pseudo-random number generators (such as precision and periodicity) vary widely. See [.Random.seed](#) for more information on R's random number generation algorithms.

Examples

```
u <- runif(20)

## The following relations always hold :
punif(u) == u
dunif(u) == 1

var(runif(10000)) #- ~ = 1/12 = .08333
```

uniroot

One Dimensional Root (Zero) Finding

Description

The function uniroot searches the interval from lower to upper for a root (i.e., zero) of the function f with respect to its first argument.

Setting extendInt to a non-"no" string, means searching for the correct interval = c(lower,upper) if sign(f(x)) does not satisfy the requirements at the interval end points; see the 'Details' section.

Usage

```
uniroot(f, interval, ...,
        lower = min(interval), upper = max(interval),
        f.lower = f(lower, ...), f.upper = f(upper, ...),
        extendInt = c("no", "yes", "downX", "upX"), check.conv = FALSE,
        tol = .Machine$double.eps^0.25, maxiter = 1000, trace = 0)
```

Arguments

| | |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>f</code> | the function for which the root is sought. |
| <code>interval</code> | a vector containing the end-points of the interval to be searched for the root. |
| <code>...</code> | additional named or unnamed arguments to be passed to <code>f</code> |
| <code>lower, upper</code> | the lower and upper end points of the interval to be searched. |
| <code>f.lower, f.upper</code> | the same as <code>f(upper)</code> and <code>f(lower)</code> , respectively. Passing these values from the caller where they are often known is more economical as soon as <code>f()</code> contains non-trivial computations. |
| <code>extendInt</code> | character string specifying if the interval <code>c(lower, upper)</code> should be extended or directly produce an error when <code>f()</code> does not have differing signs at the end-points. The default, "no", keeps the search interval and hence produces an error. Can be abbreviated. |
| <code>check.conv</code> | logical indicating whether a convergence warning of the underlying <code>uniroot</code> should be caught as an error and if non-convergence in <code>maxiter</code> iterations should be an error instead of a warning. |
| <code>tol</code> | the desired accuracy (convergence tolerance). |
| <code>maxiter</code> | the maximum number of iterations. |
| <code>trace</code> | integer number; if positive, tracing information is produced. Higher values giving more details. |

Details

Note that arguments after `...` must be matched exactly.

Either `interval` or both `lower` and `upper` must be specified: the upper endpoint must be strictly larger than the lower endpoint. The function values at the endpoints must be of opposite signs (or zero), for `extendInt="no"`, the default. Otherwise, if `extendInt="yes"`, the interval is extended on both sides, in search of a sign change, i.e., until the search interval $[l, u]$ satisfies $f(l) \cdot f(u) \leq 0$.

If it is *known how* f changes sign at the root x_0 , that is, if the function is increasing or decreasing there, `extendInt` can (and typically should) be specified as "upX" (for "upward crossing") or "downX", respectively. Equivalently, define $S := \pm 1$, to require $S = \text{sign}(f(x_0 + \epsilon))$ at the solution. In that case, the search interval $[l, u]$ possibly is extended to be such that $S \cdot f(l) \leq 0$ and $S \cdot f(u) \geq 0$.

`uniroot()` uses Fortran subroutine `zero1n` (from Netlib) based on algorithms given in the reference below. They assume a continuous function (which then is known to have at least one root in the interval).

Convergence is declared either if $f(x) == 0$ or the change in x for one step of the algorithm is less than `tol` (plus an allowance for representation error in x).

If the algorithm does not converge in `maxiter` steps, a warning is printed and the current approximation is returned.

`f` will be called as `f(x, ...)` for a numeric value of x .

The argument passed to `f` has special semantics and used to be shared between calls. The function should not copy it.

Value

A list with at least five components: `root` and `f.root` give the location of the root and the value of the function evaluated at that point. `iter` and `estim.prec` give the number of iterations used and an approximate estimated precision for root. (If the root occurs at one of the endpoints, the estimated precision is NA.) `init.it` contains the number of *initial* `extendInt` iterations if there were any and is NA otherwise. In the case of such `extendInt` iterations, `iter` contains the sum of these and the `zeroIn` iterations.

Further components may be added in the future.

Source

Based on ‘`zeroIn.c`’ in <https://netlib.org/c/brent.shar>.

[polyroot](#) for all complex roots of a polynomial; [optimize](#), [nlm](#).

Examples

```
require(utils) # for str

## some platforms hit zero exactly on the first step:
## if so the estimated precision is 2/3.
f <- function(x, a) x - a
str(xmin <- uniroot(f, c(0, 1), tol = 0.0001, a = 1/3))

## handheld calculator example: fixed point of cos(.):
uniroot(function(x) cos(x) - x, lower = -pi, upper = pi, tol = 1e-9)$root

str(uniroot(function(x) x*(x^2-1) + .5, lower = -2, upper = 2,
               tol = 0.0001))
str(uniroot(function(x) x*(x^2-1) + .5, lower = -2, upper = 2,
               tol = 1e-10))

## Find the smallest value x for which exp(x) > 0 (numerically):
r <- uniroot(function(x) 1e80*exp(x) - 1e-300, c(-1000, 0), tol = 1e-15)
str(r, digits.d = 15) # around -745, depending on the platform.

exp(r$root)      # = 0, but not for r$root * 0.999...
minexp <- r$root * (1 - 10*.Machine$double.eps)
exp(minexp)      # typically denormalized

##--- uniroot() with new interval extension + checking features: -----
f1 <- function(x) (121 - x^2)/(x^2+1)
```

```

f2 <- function(x) exp(-x)*(x - 12)

try(uniroot(f1, c(0,10)))
try(uniroot(f2, c(0, 2)))
##--> error: f() .. end points not of opposite sign

## where as 'extendInt="yes"' simply first enlarges the search interval:
u1 <- uniroot(f1, c(0,10),extendInt="yes", trace=1)
u2 <- uniroot(f2, c(0,2), extendInt="yes", trace=2)
stopifnot(all.equal(u1$root, 11, tolerance = 1e-5),
          all.equal(u2$root, 12, tolerance = 6e-6))

## The *danger* of interval extension:
## No way to find a zero of a positive function, but
## numerically,  $f(-|M|)$  becomes zero :
u3 <- uniroot(exp, c(0,2), extendInt="yes", trace=TRUE)

## Nonsense example (must give an error):
tools::assertCondition( uniroot(function(x) 1, 0:1, extendInt="yes"),
                        "error", verbose=TRUE)

## Convergence checking :
sinc <- function(x) ifelse(x == 0, 1, sin(x)/x)
curve(sinc, -6,18); abline(h=0,v=0, lty=3, col=adjustcolor("gray", 0.8))

uniroot(sinc, c(0,5), extendInt="yes", maxiter=4) #-> "just" a warning

## now with check.conv=TRUE, must signal a convergence error :

uniroot(sinc, c(0,5), extendInt="yes", maxiter=4, check.conv=TRUE)

### Weibull cumulative hazard (example origin, Ravi Varadhan):
cumhaz <- function(t, a, b) b * (t/b)^a
froot <- function(x, u, a, b) cumhaz(x, a, b) - u

n <- 1000
u <- -log(runif(n))
a <- 1/2
b <- 1
## Find failure times
ru <- sapply(u, function(x)
  uniroot(froot, u=x, a=a, b=b, interval= c(1.e-14, 1e04),
    extendInt="yes")$root)
ru2 <- sapply(u, function(x)
  uniroot(froot, u=x, a=a, b=b, interval= c(0.01, 10),
    extendInt="yes")$root)
stopifnot(all.equal(ru, ru2, tolerance = 6e-6))

r1 <- uniroot(froot, u= 0.99, a=a, b=b, interval= c(0.01, 10),
  extendInt="up")
stopifnot(all.equal(0.99, cumhaz(r1$root, a=a, b=b)))

```

```
## An error if 'extendInt' assumes "wrong zero-crossing direction":
uniroot(froot, u= 0.99, a=a, b=b, interval= c(0.1, 10), extendInt="down")
```

update

Update and Re-fit a Model Call

Description

update will update and (by default) re-fit a model. It does this by extracting the call stored in the object, updating the call and (by default) evaluating that call. Sometimes it is useful to call update with only one argument, for example if the data frame has been corrected.

“Extracting the call” in update() and similar functions uses getCall() which itself is a (S3) generic function with a default method that simply gets x\$call.

Because of this, update() will often work (via its default method) on new model classes, either automatically, or by providing a simple getCall() method for that class.

Usage

```
update(object, ...)
## Default S3 method:
update(object, formula., ..., evaluate = TRUE)

getCall(x, ...)
```

Arguments

| | |
|-----------|------------------------------------------------------------------------------------------------------------------|
| object, x | An existing fit from a model function such as lm, glm and many others. |
| formula. | Changes to the formula – see update.formula for details. |
| ... | Additional arguments to the call, or arguments with changed values. Use name = NULL to remove the argument name. |
| evaluate | If true evaluate the new call else return the call. |

Value

If evaluate = TRUE the fitted object, otherwise the updated call.

References

options(oldcon)
```

| | |
|----------------|-----------------------|
| update.formula | <i>Model Updating</i> |
|----------------|-----------------------|

Description

update.formula is used to update model formulae. This typically involves adding or dropping terms, but updates can be more general.

Usage

```
## S3 method for class 'formula'
update(old, new, ...)
```

Arguments

| | |
|-----|------------------------------------------------------------|
| old | a model formula to be updated. |
| new | a formula giving a template which specifies how to update. |
| ... | further arguments passed to or from other methods. |

Details

Either or both of old and new can be objects such as length-one character vectors which can be coerced to a formula via [as.formula](#).

The function works by first identifying the *left-hand side* and *right-hand side* of the old formula. It then examines the new formula and substitutes the *lhs* of the old formula for any occurrence of ‘.’ on the left of new, and substitutes the *rhs* of the old formula for any occurrence of ‘.’ on the right of new. The result is then simplified via [terms.formula](#)(simplify = TRUE).

Value

The updated formula is returned. The environment of the result is that of old.

See Also

[terms, model.matrix.](#)

Examples

```
update(y ~ x,      ~ . + x2) #> y ~ x + x2
update(y ~ x, log(.) ~ . ) #> log(y) ~ x
update(. ~ u+v, res ~ . ) #> res ~ u + v
```

var.test

F Test to Compare Two Variances

Description

Performs an F test to compare the variances of two samples from normal populations.

Usage

```
var.test(x, ...)

## Default S3 method:
var.test(x, y, ratio = 1,
         alternative = c("two.sided", "less", "greater"),
         conf.level = 0.95, ...)

## S3 method for class 'formula'
var.test(formula, data, subset, na.action, ...)
```

Arguments

| | |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x, y | numeric vectors of data values, or fitted linear model objects (inheriting from class "lm"). |
| ratio | the hypothesized ratio of the population variances of x and y. |
| alternative | a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter. |
| conf.level | confidence level for the returned confidence interval. |
| formula | a formula of the form lhs ~ rhs where lhs is a numeric variable giving the data values and rhs a factor with two levels giving the corresponding groups. |
| data | an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula). |
| subset | an optional vector specifying a subset of observations to be used. |
| na.action | a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action"). |
| ... | further arguments to be passed to or from methods. |

Details

The null hypothesis is that the ratio of the variances of the populations from which x and y were drawn, or in the data to which the linear models x and y were fitted, is equal to `ratio`.

Value

A list with class "htest" containing the following components:

| | |
|--------------------------|-------------------------------------------------------------------------|
| <code>statistic</code> | the value of the F test statistic. |
| <code>parameter</code> | the degrees of the freedom of the F distribution of the test statistic. |
| <code>p.value</code> | the p-value of the test. |
| <code>conf.int</code> | a confidence interval for the ratio of the population variances. |
| <code>estimate</code> | the ratio of the sample variances of x and y . |
| <code>null.value</code> | the ratio of population variances under the null. |
| <code>alternative</code> | a character string describing the alternative hypothesis. |
| <code>method</code> | the character string "F test to compare two variances". |
| <code>data.name</code> | a character string giving the names of the data. |

See Also

[bartlett.test](#) for testing homogeneity of variances in more than two samples from normal distributions; [ansari.test](#) and [mood.test](#) for two rank based (nonparametric) two-sample tests for difference in scale.

Examples

```
x <- rnorm(50, mean = 0, sd = 2)
y <- rnorm(30, mean = 1, sd = 1)
var.test(x, y)           # Do x and y have the same variance?
var.test(lm(x ~ 1), lm(y ~ 1)) # The same.
```

varimax

Rotation Methods for Factor Analysis

Description

These functions 'rotate' loading matrices in factor analysis.

Usage

```
varimax(x, normalize = TRUE, eps = 1e-5)
promax(x, m = 4)
```

Arguments

| | |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code> | A loadings matrix, with p rows and $k < p$ columns |
| <code>m</code> | The power used the target for promax. Values of 2 to 4 are recommended. |
| <code>normalize</code> | logical. Should Kaiser normalization be performed? If so the rows of <code>x</code> are re-scaled to unit length before rotation, and scaled back afterwards. |
| <code>eps</code> | The tolerance for stopping: the relative change in the sum of singular values. |

Details

These seek a ‘rotation’ of the factors $x \%*\% T$ that aims to clarify the structure of the loadings matrix. The matrix T is a rotation (possibly with reflection) for `varimax`, but a general linear transformation for `promax`, with the variance of the factors being preserved.

Value

A list with components

| | |
|-----------------------|-------------------------------------------------------------------------------|
| <code>loadings</code> | The ‘rotated’ loadings matrix, $x \%*\% \text{rotmat}$, of class “loadings”. |
| <code>rotmat</code> | The ‘rotation’ matrix. |

varimax(loadings(fa), normalize = FALSE)
promax(loadings(fa))
```

vcov

*Calculate Variance-Covariance Matrix for a Fitted Model Object***Description**

Returns the variance-covariance matrix of the main parameters of a fitted model object. The “main” parameters of model correspond to those returned by `coef`, and typically do not contain a nuisance scale parameter (`sigma`).

Usage

```
vcov(object, ...)
## S3 method for class 'lm'
vcov(object, complete = TRUE, ...)
## and also for '[summary.]glm' and 'mlm'
## S3 method for class 'aov'
vcov(object, complete = FALSE, ...)

.vcov.aliased(alias, vc, complete = TRUE)
```

Arguments

| | |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | a fitted model object, typically. Sometimes also a <code>summary()</code> object of such a fitted model. |
| <code>complete</code> | for the <code>aov</code> , <code>lm</code> , <code>glm</code> , <code>mlm</code> , and where applicable <code>summary.lm</code> etc methods: logical indicating if the full variance-covariance matrix should be returned also in case of an over-determined system where some coefficients are undefined and <code>coef(.)</code> contains NAs correspondingly. When <code>complete = TRUE</code> , <code>vcov()</code> is compatible with <code>coef()</code> also in this singular case. |
| <code>...</code> | additional arguments for method functions. For the <code>glm</code> method this can be used to pass a dispersion parameter. |
| <code>alias</code> | a logical vector typically identical to <code>is.na(coef(.))</code> indicating which coefficients are ‘aliased’. |
| <code>vc</code> | a variance-covariance matrix, typically “incomplete”, i.e., with no rows and columns for aliased coefficients. |

Details

`vcov()` is a generic function and functions with names beginning in `vcov.` will be methods for this function. Classes with methods for this function include: `lm`, `mlm`, `glm`, `nls`, `summary.lm`, `summary.glm`, `negbin`, `polr`, `rlm` (in package **MASS**), `multinom` (in package **nnet**) `gls`, `lme` (in package **nlme**), `coxph` and `survreg` (in package **survival**).

(`vcov()` methods for summary objects allow more efficient and still encapsulated access when both `summary(mod)` and `vcov(mod)` are needed.)

`.vcov.aliased()` is an auxiliary function useful for `vcov` method implementations which have to deal with singular model fits encoded via NA coefficients: It augments a `vcov`-matrix `vc` by NA

rows and columns where needed, i.e., when some entries of `aliased` are true and `vc` is of smaller dimension than `length(aliased)`.

Value

A matrix of the estimated covariances between the parameter estimates in the linear or non-linear predictor of the model. This should have row and column names corresponding to the parameter names given by the `coef` method.

When some coefficients of the (linear) model are undetermined and hence NA because of linearly dependent terms (or an “over specified” model), also called “aliased”, see [alias](#), then since R version 3.5.0, `vcov()` (iff `complete = TRUE`, i.e., by default for `lm` etc, but not for `aov`) contains corresponding rows and columns of NAs, wherever `coef()` has always contained such NAs.

Weibull

The Weibull Distribution

Description

Density, distribution function, quantile function and random generation for the Weibull distribution with parameters shape and scale.

Usage

```
dweibull(x, shape, scale = 1, log = FALSE)
pweibull(q, shape, scale = 1, lower.tail = TRUE, log.p = FALSE)
qweibull(p, shape, scale = 1, lower.tail = TRUE, log.p = FALSE)
rweibull(n, shape, scale = 1)
```

Arguments

| | |
|---------------------------|-----------------------------------------------------------------------------------------------------------|
| <code>x, q</code> | vector of quantiles. |
| <code>p</code> | vector of probabilities. |
| <code>n</code> | number of observations. If <code>length(n) > 1</code> , the length is taken to be the number required. |
| <code>shape, scale</code> | shape and scale parameters, the latter defaulting to 1. |
| <code>log, log.p</code> | logical; if TRUE, probabilities <code>p</code> are given as <code>log(p)</code> . |
| <code>lower.tail</code> | logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$. |

Details

The Weibull distribution with shape parameter a and scale parameter σ has density given by

$$f(x) = (a/\sigma)(x/\sigma)^{a-1} \exp(-(x/\sigma)^a)$$

for $x > 0$. The cumulative distribution function is $F(x) = 1 - \exp(-(x/\sigma)^a)$ on $x > 0$, the mean is $E(X) = \sigma\Gamma(1 + 1/a)$, and the $Var(X) = \sigma^2(\Gamma(1 + 2/a) - (\Gamma(1 + 1/a))^2)$.

Value

dweibull gives the density, pweibull gives the distribution function, qweibull gives the quantile function, and rweibull generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by n for rweibull, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.

Note

The cumulative hazard $H(t) = -\log(1 - F(t))$ is

```
-pweibull(t, a, b, lower = FALSE, log = TRUE)
```

which is just $H(t) = (t/b)^a$.

Source

[dpq]weibull are calculated directly from the definitions. rweibull uses inversion.

[Distributions](#) for other standard distributions, including the [Exponential](#) which is a special case of the Weibull distribution.

Examples

```
x <- c(0, rlnorm(50))
all.equal(dweibull(x, shape = 1), dexp(x))
all.equal(pweibull(x, shape = 1, scale = pi), pexp(x, rate = 1/pi))
## Cumulative hazard H():
all.equal(pweibull(x, 2.5, pi, lower.tail = FALSE, log.p = TRUE),
          -(x/pi)^2.5, tolerance = 1e-15)
all.equal(qweibull(x/11, shape = 1, scale = pi), qexp(x/11, rate = 1/pi))
```

weighted.mean*Weighted Arithmetic Mean*

Description

Compute a weighted mean.

Usage

```
weighted.mean(x, w, ...)  
  
## Default S3 method:  
weighted.mean(x, w, ..., na.rm = FALSE)
```

Arguments

| | |
|-------|-------------------------------------------------------------------------------------------------------|
| x | an object containing the values whose weighted mean is to be computed. |
| w | a numerical vector of weights the same length as x giving the weights to use for elements of x. |
| ... | arguments to be passed to or from methods. |
| na.rm | a logical value indicating whether NA values in x should be stripped before the computation proceeds. |

Details

This is a generic function and methods can be defined for the first argument x: apart from the default methods there are methods for the date-time classes "POSIXct", "POSIXlt", "difftime" and "Date". The default method will work for any numeric-like object for which [, multiplication, division and [sum](#) have suitable methods, including complex vectors.

If w is missing then all elements of x are given the same weight, otherwise the weights are normalized to sum to one (if possible: if their sum is zero or infinite the value is likely to be NaN).

Missing values in w are not handled specially and so give a missing value as the result. However, zero weights *are* handled specially and the corresponding x values are omitted from the sum.

Value

For the default method, a length-one numeric vector.

See Also

[mean](#)

Examples

```
## GPA from Siegel 1994
wt <- c(5, 5, 4, 1)/15
x <- c(3.7, 3.3, 3.5, 2.8)
xm <- weighted.mean(x, wt)
```

| | |
|--------------------|-----------------------------------|
| weighted.residuals | <i>Compute Weighted Residuals</i> |
|--------------------|-----------------------------------|

Description

Computed weighted residuals from a linear model fit.

Usage

```
weighted.residuals(obj, drop0 = TRUE)
```

Arguments

| | |
|-------|--------------------------------------------------------------------------|
| obj | R object, typically of class lm or glm . |
| drop0 | logical. If TRUE, drop all cases with weights == 0. |

Details

Weighted residuals are based on the deviance residuals, which for a [lm](#) fit are the raw residuals R_i multiplied by $\sqrt{w_i}$, where w_i are the weights as specified in [lm](#)'s call.

Dropping cases with weights zero is compatible with [influence](#) and related functions.

Value

Numeric vector of length n' , where n' is the number of non-0 weights (drop0 = TRUE) or the number of observations, otherwise.

See Also

[residuals](#), [lm.influence](#), etc.

Examples

```
## following on from example(lm)

all.equal(weighted.residuals(lm.D9),
          residuals(lm.D9))

x <- 1:10
w <- 0:9
y <- rnorm(x)
weighted.residuals(lmxy <- lm(y ~ x, weights = w))
weighted.residuals(lmxy, drop0 = FALSE)
```

`weights`*Extract Model Weights*

Description

`weights` is a generic function which extracts fitting weights from objects returned by modeling functions.

Methods can make use of [napredict](#) methods to compensate for the omission of missing values. The default methods does so.

Usage

```
weights(object, ...)
```

Arguments

| | |
|---------------------|--------------------------------------------------------------------|
| <code>object</code> | an object for which the extraction of model weights is meaningful. |
| <code>...</code> | other arguments passed to methods. |

Value

Weights extracted from the object `object`: the default method looks for component "weights" and if not NULL calls [napredict](#) on it.

[weights.glm](#)

`wilcox.test`*Wilcoxon Rank Sum and Signed Rank Tests*

Description

Performs one- and two-sample Wilcoxon tests on vectors of data; the latter is also known as ‘Mann-Whitney’ test.

Usage

```
wilcox.test(x, ...)

## Default S3 method:
wilcox.test(x, y = NULL,
            alternative = c("two.sided", "less", "greater"),
            mu = 0, paired = FALSE, exact = NULL, correct = TRUE,
            conf.int = FALSE, conf.level = 0.95,
            tol.root = 1e-4, digits.rank = Inf, ...)

## S3 method for class 'formula'
wilcox.test(formula, data, subset, na.action = na.pass, ...)
```

Arguments

| | |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x | numeric vector of data values. Non-finite (e.g., infinite or missing) values will be omitted. |
| y | an optional numeric vector of data values: as with x non-finite values will be omitted. |
| alternative | a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter. |
| mu | a number specifying an optional parameter used to form the null hypothesis. See 'Details'. |
| paired | a logical indicating whether you want a paired test. |
| exact | a logical indicating whether an exact p-value should be computed. |
| correct | a logical indicating whether to apply continuity correction in the normal approximation for the p-value. |
| conf.int | a logical indicating whether a confidence interval should be computed. |
| conf.level | confidence level of the interval. |
| tol.root | (when conf.int is true:) a positive numeric tolerance, used in <code>uniroot(*, tol=tol.root)</code> calls. |
| digits.rank | a number; if finite, <code>rank(signif(r, digits.rank))</code> will be used to compute ranks for the test statistic instead of (the default) <code>rank(r)</code> . |
| formula | a formula of the form <code>lhs ~ rhs</code> where lhs is a numeric variable giving the data values and rhs either 1 for a one-sample or paired test or a factor with two levels giving the corresponding groups. If lhs is of class "Pair" and rhs is 1, a paired test is done, see Examples. |
| data | an optional matrix or data frame (or similar: see <code>model.frame</code>) containing the variables in the formula formula. By default the variables are taken from <code>environment(formula)</code> . |
| subset | an optional vector specifying a subset of observations to be used. |
| na.action | a function which indicates what should happen when the data contain NAs. |
| ... | further arguments to be passed to or from methods. For the formula method, this includes arguments of the default method, but not paired. |

Details

The formula interface is only applicable for the 2-sample tests.

If only x is given, or if both x and y are given and `paired` is `TRUE`, a Wilcoxon signed rank test of the null that the distribution of x (in the one sample case) or of $x - y$ (in the paired two sample case) is symmetric about μ is performed.

Otherwise, if both x and y are given and `paired` is `FALSE`, a Wilcoxon rank sum test (equivalent to the Mann-Whitney test: see the Note) is carried out. In this case, the null hypothesis is that the distributions of x and y differ by a location shift of μ and the alternative is that they differ by some other location shift (and the one-sided alternative "greater" is that x is shifted to the right of y).

By default (if `exact` is not specified), an exact p-value is computed if the samples contain less than 50 finite values and there are no ties. Otherwise, a normal approximation is used.

For stability reasons, it may be advisable to use rounded data or to set `digits.rank = 7`, say, such that determination of ties does not depend on very small numeric differences (see the example).

Optionally (if argument `conf.int` is true), a nonparametric confidence interval and an estimator for the pseudomedian (one-sample case) or for the difference of the location parameters $x - y$ is computed. (The pseudomedian of a distribution F is the median of the distribution of $(u + v)/2$, where u and v are independent, each with distribution F . If F is symmetric, then the pseudomedian and median coincide. See Hollander & Wolfe (1973), page 34.) Note that in the two-sample case the estimator for the difference in location parameters does **not** estimate the difference in medians (a common misconception) but rather the median of the difference between a sample from x and a sample from y .

If exact p-values are available, an exact confidence interval is obtained by the algorithm described in Bauer (1972), and the Hodges-Lehmann estimator is employed. Otherwise, the returned confidence interval and point estimate are based on normal approximations. These are continuity-corrected for the interval but *not* the estimate (as the correction depends on the alternative).

With small samples it may not be possible to achieve very high confidence interval coverages. If this happens a warning will be given and an interval with lower coverage will be substituted.

When x (and y if applicable) are valid, the function now always returns, also in the `conf.int = TRUE` case when a confidence interval cannot be computed, in which case the interval boundaries and sometimes the estimate now contain `NaN`.

Value

A list with class "htest" containing the following components:

| | |
|--------------------------|-------------------------------------------------------------------------------------------------------------|
| <code>statistic</code> | the value of the test statistic with a name describing it. |
| <code>parameter</code> | the parameter(s) for the exact distribution of the test statistic. |
| <code>p.value</code> | the p-value for the test. |
| <code>null.value</code> | the location parameter μ . |
| <code>alternative</code> | a character string describing the alternative hypothesis. |
| <code>method</code> | the type of test applied. |
| <code>data.name</code> | a character string giving the names of the data. |
| <code>conf.int</code> | a confidence interval for the location parameter. (Only present if argument <code>conf.int = TRUE</code> .) |

estimate an estimate of the location parameter. (Only present if argument `conf.int = TRUE`.)

Warning

This function can use large amounts of memory and stack (and even crash R if the stack limit is exceeded) if `exact = TRUE` and one sample is large (several thousands or more).

Note

The literature is not unanimous about the definitions of the Wilcoxon rank sum and Mann-Whitney tests. The two most common definitions correspond to the sum of the ranks of the first sample with the minimum value $(m(m+1)/2)$ for a first sample of size m subtracted or not: R subtracts. It seems Wilcoxon's original paper used the unadjusted sum of the ranks but subsequent tables subtracted the minimum.

R's value can also be computed as the number of all pairs $(x[i], y[j])$ for which $y[j]$ is not greater than $x[i]$, the most common definition of the Mann-Whitney test.

```

Wilcoxon

Distribution of the Wilcoxon Rank Sum Statistic

Description

Density, distribution function, quantile function and random generation for the distribution of the Wilcoxon rank sum statistic obtained from samples with size m and n , respectively.

Usage

```

dwilcox(x, m, n, log = FALSE)
pwilcox(q, m, n, lower.tail = TRUE, log.p = FALSE)
qwilcox(p, m, n, lower.tail = TRUE, log.p = FALSE)
rwilcox(nn, m, n)

```

Arguments

| | |
|-------------------------|------------------------------------------------------------------------------------------------------------|
| <code>x, q</code> | vector of quantiles. |
| <code>p</code> | vector of probabilities. |
| <code>nn</code> | number of observations. If <code>length(nn) > 1</code> , the length is taken to be the number required. |
| <code>m, n</code> | numbers of observations in the first and second sample, respectively. Can be vectors of positive integers. |
| <code>log, log.p</code> | logical; if TRUE, probabilities <code>p</code> are given as $\log(p)$. |
| <code>lower.tail</code> | logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$. |

Details

This distribution is obtained as follows. Let x and y be two random, independent samples of size m and n . Then the Wilcoxon rank sum statistic is the number of all pairs $(x[i], y[j])$ for which $y[j]$ is not greater than $x[i]$. This statistic takes values between 0 and $m * n$, and its mean and variance are $m * n / 2$ and $m * n * (m + n + 1) / 12$, respectively.

If any of the first three arguments are vectors, the recycling rule is used to do the calculations for all combinations of the three up to the length of the longest vector.

Value

`dwilcox` gives the density, `pwilcox` gives the distribution function, `qwilcox` gives the quantile function, and `rwilcox` generates random deviates.

The length of the result is determined by `nn` for `rwilcox`, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than `nn` are recycled to the length of the result. Only the first elements of the logical arguments are used.

Warning

These functions can use large amounts of memory and stack (and even crash R if the stack limit is exceeded and stack-checking is not in place) if one sample is large (several thousands or more).

Note

S-PLUS used a different (but equivalent) definition of the Wilcoxon statistic: see [wilcox.test](#) for details.

Author(s)

Kurt Hornik

Source

These ("d","p","q") are calculated via recursion, based on `cwilcox(k, m, n)`, the number of choices with statistic k from samples of size m and n , which is itself calculated recursively and the results cached. Then `dwilcox` and `pwilcox` sum appropriate values of `cwilcox`, and `qwilcox` is based on inversion.

`rwilcox` generates a random permutation of ranks and evaluates the statistic. Note that it is based on the same C code as `sample()`, and hence is determined by `.Random.seed`, notably from `RNGkind(sample.kind = ..)` which changed with R version 3.6.0.

See Also

`wilcox.test` to calculate the statistic from data, find p values and so on.

Distributions for standard distributions, including `dsignrank` for the distribution of the *one-sample* Wilcoxon signed rank statistic.

Examples

```
require(graphics)

x <- -1:(4*6 + 1)
fx <- dwilcox(x, 4, 6)
Fx <- pwilcox(x, 4, 6)

layout(rbind(1,2), widths = 1, heights = c(3,2))
plot(x, fx, type = "h", col = "violet",
     main = "Probabilities (density) of Wilcoxon-Statist.(n=6, m=4)")
plot(x, Fx, type = "s", col = "blue",
     main = "Distribution of Wilcoxon-Statist.(n=6, m=4)")
abline(h = 0:1, col = "gray20", lty = 2)
layout(1) # set back

N <- 200
hist(U <- rwilcox(N, m = 4, n = 6), breaks = 0:25 - 1/2,
     border = "red", col = "pink", sub = paste("N =", N))
mtext("N * f(x), f() = true \"density\"", side = 3, col = "blue")

points(x, N*fx, cex = 2)

## Better is a Quantile-Quantile Plot
qqplot(U, qw <- qwilcox((1:N - 1/2)/N, m = 4, n = 6),
      main = paste("Q-Q-Plot of empirical and theoretical quantiles",
                    "Wilcoxon Statistic, (m=4, n=6)", sep = "\n"))
n <- as.numeric(names(print(tU <- table(U))))
text(n+.2, n+.5, labels = tU, col = "red")
```

window

*Time (Series) Windows***Description**

window is a generic function which extracts the subset of the object `x` observed between the times `start` and `end`. If a frequency is specified, the series is then re-sampled at the new frequency.

Usage

```

window(x, ...)
## S3 method for class 'ts'
window(x, ...)
## Default S3 method:
window(x, start = NULL, end = NULL,
       frequency = NULL, deltat = NULL, extend = FALSE, ts.eps = getOption("ts.eps"), ...)

window(x, ...) <- value
## S3 replacement method for class 'ts'
window(x, start, end, frequency, deltat, ...) <- value

```

Arguments

| | |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code> | a time-series (or other object if not replacing values). |
| <code>start</code> | the start time of the period of interest. |
| <code>end</code> | the end time of the period of interest. |
| <code>frequency, deltat</code> | the new frequency can be specified by either (or both if they are consistent). |
| <code>extend</code> | logical. If true, the <code>start</code> and <code>end</code> values are allowed to extend the series. If false, attempts to extend the series give a warning and are ignored. |
| <code>ts.eps</code> | time series comparison tolerance. Frequencies are considered equal if their absolute difference is less than <code>ts.eps</code> and boundaries (length-1 versions of <code>start</code> and <code>end</code>) are checked with <code>fuzz ts.eps/frequency(x)</code> . |
| <code>...</code> | further arguments passed to or from other methods. |
| <code>value</code> | replacement values. |

Details

The `start` and `end` times can be specified as for [ts](#). If there is no observation at the new `start` or `end`, the immediately following (`start`) or preceding (`end`) observation time is used.

The replacement function has a method for `ts` objects, and is allowed to extend the series (with a warning). There is no default method.

Value

The value depends on the method. `window.default` will return a vector or matrix with an appropriate `tsp` attribute.

`window.ts` differs from `window.default` only in ensuring the result is a `ts` object.

If `extend = TRUE` the series will be padded with NAs if needed.

`time`, `ts`.

Examples

```
window(presidents, 1960, c(1969,4)) # values in the 1960's
window(presidents, deltat = 1) # All Qtr1s
window(presidents, start = c(1945,3), deltat = 1) # All Qtr3s
window(presidents, 1944, c(1979,2), extend = TRUE)

pres <- window(presidents, 1945, c(1949,4)) # values in the 1940's
window(pres, 1945.25, 1945.50) <- c(60, 70)
window(pres, 1944, 1944.75) <- 0 # will generate a warning
window(pres, c(1945,4), c(1949,4), frequency = 1) <- 85:89
pres
```

xtabs

Cross Tabulation

Description

Create a contingency table (optionally a sparse matrix) from cross-classifying factors, usually contained in a data frame, using a formula interface.

Usage

```
xtabs(formula = ~., data = parent.frame(), subset, sparse = FALSE,
      na.action, na.rm = FALSE, addNA = FALSE,
      exclude = if(!addNA) c(NA, NaN), drop.unused.levels = FALSE)

## S3 method for class 'xtabs'
print(x, na.print = "", ...)
```

Arguments

| | |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula | a formula object with the cross-classifying variables (separated by +) on the right-hand side (or an object which can be coerced to a formula). Interactions are not allowed. On the left-hand side, one may optionally give a vector or a matrix of counts; in the latter case, the columns are interpreted as corresponding to the levels of a variable. This is useful if the data have already been tabulated, see the examples below. |
| data | an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from <code>environment(formula)</code> . |
| subset | an optional vector specifying a subset of observations to be used. |
| sparse | logical specifying if the result should be a <i>sparse</i> matrix, i.e., inheriting from sparseMatrix . Only works for two factors (since there are no higher-order sparse array classes yet). |
| na.action | a function which indicates what should happen when the variables in formula (or subset) contain NAs. Defaults to na.pass , so <code>na.rm</code> and <code>addNA</code> , respectively, control the handling of missing values for the two sides of the formula. Using na.omit removes any incomplete cases. |
| na.rm | logical: should missing values on the left-hand side of the formula be treated as zero when computing the sum ? |
| addNA | logical indicating if NAs in the factors should get a separate level and be counted, using addNA (*, ifany=TRUE). This has no effect if <code>na.action = na.omit</code> . |
| exclude | a vector of values to be excluded when forming the set of levels of the classifying factors. |
| drop.unused.levels | a logical indicating whether to drop unused levels in the classifying factors. If this is FALSE and there are unused levels, the table will contain zero marginals, and a subsequent chi-squared test for independence of the factors will not work. |
| x | an object of class "xtabs". |
| na.print | character string (or NULL) indicating how NA are printed. The default ("") does not show NAs clearly, and <code>na.print = "NA"</code> maybe advisable instead. |
| ... | further arguments passed to or from other methods. |

Details

There is a summary method for contingency table objects created by `table` or `xtabs`(*, `sparse = FALSE`), which gives basic information and performs a chi-squared test for independence of factors (note that the function [chisq.test](#) currently only handles 2-d tables).

If a left-hand side is given in formula, its entries are simply summed over the cells corresponding to the right-hand side; this also works if the LHS does not give counts.

For variables in formula which are factors, `exclude` must be specified explicitly; the default exclusions will not be used.

In R versions before 3.4.0, e.g., when `na.action = na.pass`, sometimes zeroes (0) were returned instead of NAs.

In R versions before 4.4.0, when `!addNA` as by default, the default `na.action` was [na.omit](#), effectively treating missing counts as zero.

Value

By default, when `sparse = FALSE`, a contingency table in array representation of S3 class `c("xtabs", "table")`, with a "call" attribute storing the matched call.

When `sparse = TRUE`, a sparse numeric matrix, specifically an object of S4 class `dgTMatrix` from package **Matrix**.

See Also

`table` for traditional cross-tabulation, and `as.data.frame.table` which is the inverse operation of `xtabs` (see the DF example below).

`sparseMatrix` on sparse matrices in package **Matrix**.

Examples

```
## 'esoph' has the frequencies of cases and controls for all levels of
## the variables 'agegp', 'alcgp', and 'tobgp'.
xtabs(cbind(ncases, ncontrols) ~ ., data = esoph)
## Output is not really helpful ... flat tables are better:
ftable(xtabs(cbind(ncases, ncontrols) ~ ., data = esoph))
## In particular if we have fewer factors ...
ftable(xtabs(cbind(ncases, ncontrols) ~ agegp, data = esoph))

## This is already a contingency table in array form.
DF <- as.data.frame(UCBAdmissions)
## Now 'DF' is a data frame with a grid of the factors and the counts
## in variable 'Freq'.
DF
## Nice for taking margins ...
xtabs(Freq ~ Gender + Admit, DF)
## And for testing independence ...
summary(xtabs(Freq ~ ., DF))

## with NA's
DN <- DF; DN[cbind(6:9, c(1:2,4,1))] <- NA
DN # 'Freq' is missing only for (Rejected, Female, B)
(xtNA <- xtabs(Freq ~ Gender + Admit, DN)) # NA prints 'invisibly'
print(xtNA, na.print = "NA") # show NA's better
xtabs(Freq ~ Gender + Admit, DN, na.rm = TRUE) # ignore missing Freq
## Use addNA = TRUE to tabulate missing factor levels:
xtabs(Freq ~ Gender + Admit, DN, addNA = TRUE)
xtabs(Freq ~ Gender + Admit, DN, addNA = TRUE, na.rm = TRUE)
## na.action = na.omit removes all rows with NAs right from the start:
xtabs(Freq ~ Gender + Admit, DN, na.action = na.omit)

## Create a nice display for the warp break data.
warpbreaks$replicate <- rep_len(1:9, 54)
ftable(xtabs(breaks ~ wool + tension + replicate, data = warpbreaks))

### ---- Sparse Examples ----

if(require("Matrix")) withAutoprint({
```

```
## similar to "nlme"s 'ergoStool' :
d.ergo <- data.frame(Type = paste0("T", rep(1:4, 9*4)),
                     Subj = gl(9, 4, 36*4))
xtabs(~ Type + Subj, data = d.ergo) # 4 replicates each
set.seed(15) # a subset of cases:
xtabs(~ Type + Subj, data = d.ergo[sample(36, 10), ], sparse = TRUE)

## Hypothetical two-level setup:
inner <- factor(sample(letters[1:25], 100, replace = TRUE))
inout <- factor(sample(LETTERS[1:5], 25, replace = TRUE))
fr <- data.frame(inner = inner, outer = inout[as.integer(inner)])
xtabs(~ inner + outer, fr, sparse = TRUE)
})
```

Chapter 11

The stats4 package

stats4-package

Statistical Functions using S4 Classes

Description

Statistical Functions using S4 classes.

Details

This package contains functions and classes for statistics using the [S version 4](#) class system.

The methods currently support maximum likelihood (function [mle\(\)](#) returning class "[mle](#)"), including methods for [logLik](#) for use with [AIC](#).

Author(s)

R Core Team and contributors worldwide

Maintainer: R Core Team <R-core@r-project.org>

coef-methods

Methods for Function coef in Package stats4

Description

Extract the coefficient vector from "mle" objects.

Methods

signature(object = "ANY") Generic function: see [coef](#).

signature(object = "mle") Extract the full coefficient vector (including any fixed coefficients) from the fit.

signature(object = "summary.mle") Extract the coefficient vector and standard errors from the summary of the fit.

| | |
|-----------------|-------------------------------------------------------|
| confint-methods | <i>Methods for Function confint in Package stats4</i> |
|-----------------|-------------------------------------------------------|

Description

Generate confidence intervals

Methods

signature(object = "ANY") Generic function: see [confint](#).
signature(object = "mle") First generate profile and then confidence intervals from the profile.
signature(object = "profile.mle") Generate confidence intervals based on likelihood profile.

| | |
|----------------|------------------------------------------------------|
| logLik-methods | <i>Methods for Function logLik in Package stats4</i> |
|----------------|------------------------------------------------------|

Description

Extract the maximized log-likelihood from "mle" objects.

Methods

signature(object = "ANY") Generic function: see [logLik](#).
signature(object = "mle") Extract log-likelihood from the fit.

Note

The mle method does not know about the number of observations unless nobs was specified on the call and so may not be suitable for use with [BIC](#).

| | |
|-----|--------------------------------------|
| mle | <i>Maximum Likelihood Estimation</i> |
|-----|--------------------------------------|

Description

Estimate parameters by the method of maximum likelihood.

Usage

```
mle(minuslogl, start,
    optim = stats::optim,
    method = if(!useLim) "BFGS" else "L-BFGS-B",
    fixed = list(), nobs, lower, upper, ...)
```

Arguments

| | |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <code>minuslogl</code> | Function to calculate negative log-likelihood. |
| <code>start</code> | Named list of vectors or single vector. Initial values for optimizer. By default taken from the default arguments of <code>minuslogl</code> |
| <code>optim</code> | Optimizer function. (Experimental) |
| <code>method</code> | Optimization method to use. See optim . |
| <code>fixed</code> | Named list of vectors or single vector. Parameter values to keep fixed during optimization. |
| <code>nobs</code> | optional integer: the number of observations, to be used for e.g. computing BIC . |
| <code>lower, upper</code> | Named lists of vectors or single vectors. Bounds for optim , if relevant. |
| <code>...</code> | Further arguments to pass to optim . |

Details

The `optim` optimizer is used to find the minimum of the negative log-likelihood. An approximate covariance matrix for the parameters is obtained by inverting the Hessian matrix at the optimum. By default, [optim](#) from the `stats` package is used; other optimizers need to be plug-compatible, both with respect to arguments and return values.

The function `minuslogl` should take one or several arguments, each of which can be a vector. The optimizer optimizes a function which takes a single vector argument, containing the concatenation of the arguments to `minuslogl`, removing any values that should be held fixed. This function internally unpacks the argument vector, inserts the fixed values and calls `minuslogl`.

The vector arguments `start`, `fixed`, `upper`, and `lower`, can be given in both packed and unpacked form, either as a single vector or as a list of vectors. In the latter case, you only need to specify those list elements that are actually affected. For vector arguments, including those inside lists, use a default marker for those values that you don't want to set: `NA` for `fixed` and `start`, and `+Inf`, `-Inf` for `upper`, and `lower`.

Value

An object of class [mle-class](#).

Note

Notice that the `mll` argument should calculate $-\log L$ (not $-2 \log L$). It is for the user to ensure that the likelihood is correct, and that asymptotic likelihood inference is valid.

See Also

[mle-class](#)

Examples

```
## Avoid printing to unwarranted accuracy
od <- options(digits = 5)

## Simulated EC50 experiment with count data
```

```

x <- 0:10
y <- c(26, 17, 13, 12, 20, 5, 9, 8, 5, 4, 8)

## Easy one-dimensional MLE:
nLL <- function(lambda) -sum(stats::dpois(y, lambda, log = TRUE))
fit0 <- mle(nLL, start = list(lambda = 5), nobs = NROW(y))

## sanity check --- notice that "nobs" must be input
## (not guaranteed to be meaningful for any likelihood)
stopifnot(nobs(fit0) == length(y))

# For 1D, this is preferable:
fit1 <- mle(nLL, start = list(lambda = 5), nobs = NROW(y),
           method = "Brent", lower = 1, upper = 20)

## This needs a constrained parameter space: most methods will accept NA
ll <- function(ymax = 15, xhalf = 6) {
  if(ymax > 0 && xhalf > 0)
    -sum(stats::dpois(y, lambda = ymax/(1+x/xhalf), log = TRUE))
  else NA
}
(fit <- mle(ll, nobs = length(y)))
mle(ll, fixed = list(xhalf = 6))

## Alternative using bounds on optimization
ll2 <- function(ymax = 15, xhalf = 6)
  -sum(stats::dpois(y, lambda = ymax/(1+x/xhalf), log = TRUE))
mle(ll2, lower = rep(0, 2))

AIC(fit)
BIC(fit)

summary(fit)
logLik(fit)
vcov(fit)
plot(profile(fit), absVal = FALSE)
confint(fit)

## Use bounded optimization
## The lower bounds are really > 0,
## but we use >=0 to stress-test profiling
(fit2 <- mle(ll2, lower = c(0, 0)))
plot(profile(fit2), absVal = FALSE)

## A better parametrization:
ll3 <- function(lymax = log(15), lxhalf = log(6))
  -sum(stats::dpois(y, lambda = exp(lymax)/(1+exp(lxhalf)), log = TRUE))
(fit3 <- mle(ll3))
plot(profile(fit3), absVal = FALSE)
exp(confint(fit3))

# Regression tests for bounded cases (this was broken in R 3.x)

```

```

fit4 <- mle(l1, lower = c(0, 4)) # has max on boundary
confint(fit4)

## direct check that fixed= and constraints work together
mle(l1, lower = c(0, 4), fixed=list(ymax=23)) # has max on boundary

## Linear regression using MLE
x <- 1:10
y <- c(0.48, 2.24, 2.22, 5.15, 4.64, 5.53, 7, 8.8, 7.67, 9.23)

LM_mll <- function(formula, data = environment(formula))
{
  y <- model.response(model.frame(formula, data))
  X <- model.matrix(formula, data)
  b0 <- numeric(NCOL(X))
  names(b0) <- colnames(X)
  function(b=b0, sigma=1)
    -sum(dnorm(y, X %*% b, sigma, log=TRUE))
}

mll <- LM_mll(y ~ x)

summary(lm(y~x)) # for comparison -- notice variance bias in MLE
summary(mle(mll, lower=c(-Inf,-Inf, 0.01)))
summary(mle(mll, lower=list(sigma = 0.01))) # alternative specification

confint(mle(mll, lower=list(sigma = 0.01)))
plot(profile(mle(mll, lower=list(sigma = 0.01))))

Binom_mll <- function(x, n)
{
  force(x); force(n) ## beware lazy evaluation
  function(p=.5) -dbinom(x, n, p, log=TRUE)
}

## Likelihood functions for different x.
## This code goes wrong, if force(x) is not used in Binom_mll:

curve(Binom_mll(0, 10)(p), xname="p", ylim=c(0, 10))
mll_list <- list(10)
for (x in 1:10)
  mll_list[[x]] <- Binom_mll(x, 10)
for (mll in mll_list)
  curve(mll(p), xname="p", add=TRUE)

mll <- Binom_mll(4,10)
mle(mll, lower = 1e-16, upper = 1-1e-16) # limits must be inside (0,1)

## Boundary case: This works, but fails if limits are set closer to 0 and 1
mll <- Binom_mll(0, 10)
mle(mll, lower=.005, upper=.995)

## Not run:

```

```
## We can use limits closer to the boundaries if we use the
## drop-in replacement optimr() from the optimx package.

mle(mll, lower = 1e-16, upper = 1-1e-16, optim=optimx::optimr)

## End(Not run)

options(od)
```

mle-class

Class "mle" for Results of Maximum Likelihood Estimation

Description

This class encapsulates results of a generic maximum likelihood procedure.

Objects from the Class

Objects can be created by calls of the form `new("mle", ...)`, but most often as the result of a call to `mle`.

Slots

call: Object of class "language". The call to `mle`.
coef: Object of class "numeric". Estimated parameters.
fullcoef: Object of class "numeric". Full parameter set of fixed and estimated parameters.
fixed: Object of class "numeric". Fixed parameter values (NA for non-fixed parameters).
vcov: Object of class "matrix". Approximate variance-covariance matrix.
min: Object of class "numeric". Minimum value of objective function.
details: a "list", as returned from `optim`.
minuslogl: Object of class "function". The negative loglikelihood function.
nobs: "integer" of length one. The number of observations (often NA, when not set in call explicitly).
method: Object of class "character". The optimization method used.

Methods

confint signature(object = "mle"): Confidence intervals from likelihood profiles.
logLik signature(object = "mle"): Extract maximized log-likelihood.
profile signature(fitted = "mle"): Likelihood profile generation.
nobs signature(object = "mle"): Number of observations, here simply accessing the nobs slot mentioned above.
show signature(object = "mle"): Display object briefly.

summary signature(object = "mle"): Generate object summary.

update signature(object = "mle"): Update fit.

vcov signature(object = "mle"): Extract variance-covariance matrix.

| | |
|--------------|----------------------------------------------------|
| plot-methods | <i>Methods for Function plot in Package stats4</i> |
|--------------|----------------------------------------------------|

Description

Plot profile likelihoods for "mle" objects.

Usage

```
## S4 method for signature 'profile.mle,missing'
plot(x, levels, conf = c(99, 95, 90, 80, 50)/100, nseg = 50,
     absVal = TRUE, ...)
```

Arguments

| | |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| x | an object of class "profile.mle" |
| levels | levels, on the scale of the absolute value of a t statistic, at which to interpolate intervals. Usually conf is used instead of giving levels explicitly. |
| conf | a numeric vector of confidence levels for profile-based confidence intervals on the parameters. |
| nseg | an integer value giving the number of segments to use in the spline interpolation of the profile t curves. |
| absVal | a logical value indicating whether or not the plots should be on the scale of the absolute value of the profile t. Defaults to TRUE. |
| ... | other arguments to the plot function can be passed here. |

Methods

signature(x = "ANY", y = "ANY") Generic function: see [plot](#).

signature(x = "profile.mle", y = "missing") Plot likelihood profiles for x.

Description

Profile likelihood for "mle" objects.

Usage

```
## S4 method for signature 'mle'
profile(fitted, which = 1:p, maxsteps = 100, alpha = 0.01,
        zmax = sqrt(qchisq(1 - alpha, 1L)), del = zmax/5,
        trace = FALSE, ...)
```

Arguments

| | |
|----------|-----------------------------------------------------------------------------------------------------------------------------|
| fitted | Object to be profiled |
| which | Optionally select subset of parameters to profile. |
| maxsteps | Maximum number of steps to bracket zmax. |
| alpha | Significance level corresponding to zmax, based on a Scheffe-style multiple testing interval. Ignored if zmax is specified. |
| zmax | Cutoff for the profiled value of the signed root-likelihood. |
| del | Initial stepsize on root-likelihood scale. |
| trace | Logical. Print intermediate results. |
| ... | Currently unused. |

Details

The profiling algorithm tries to find an approximately evenly spaced set of at least five parameter values (in each direction from the optimum) to cover the root-likelihood function. Some care is taken to try and get sensible results in cases of high parameter curvature. Notice that it may not always be possible to obtain the cutoff value, since the likelihood might level off.

Value

An object of class "profile.mle", see "profile.mle-class".

Methods

signature(fitted = "ANY") Generic function: see [profile](#).
signature(fitted = "mle") Profile the likelihood in the vicinity of the optimum of an "mle" object.

| | |
|-------------------|--------------------------------------------------------------------|
| profile.mle-class | <i>Class "profile.mle"; Profiling information for "mle" object</i> |
|-------------------|--------------------------------------------------------------------|

Description

Likelihood profiles along each parameter of likelihood function

Objects from the Class

Objects can be created by calls of the form `new("profile.mle", ...)`, but most often by invoking `profile` on an "mle" object.

Slots

profile: Object of class "list". List of profiles, one for each requested parameter. Each profile is a data frame with the first column called `z` being the signed square root of the $-2 \log$ likelihood ratio, and the others being the parameters with names prefixed by `par.vals`.

summary: Object of class "summary.mle". Summary of object being profiled.

Methods

confint signature(object = "profile.mle"): Use profile to generate approximate confidence intervals for parameters.

plot signature(x = "profile.mle", y = "missing"): Plot profiles for each parameter.

See Also

[mle](#), [mle-class](#), [summary.mle-class](#)

| | |
|--------------|----------------------------------------------------|
| show-methods | <i>Methods for Function show in Package stats4</i> |
|--------------|----------------------------------------------------|

Description

Show objects of classes `mle` and `summary.mle`

Methods

signature(object = "mle") Print simple summary of `mle` object. Just the coefficients and the call.

signature(object = "summary.mle") Shows call, table of coefficients and standard errors, and $-2 \log L$.

| | |
|-----------------|-------------------------------------------------------|
| summary-methods | <i>Methods for Function summary in Package stats4</i> |
|-----------------|-------------------------------------------------------|

Description

Summarize objects

Methods

signature(object = "ANY") Generic function

signature(object = "mle") Generate a summary as an object of class "summary.mle", containing estimates, asymptotic SE, and value of $-2 \log L$.

| | |
|-------------------|------------------------------------------------------|
| summary.mle-class | <i>Class "summary.mle", Summary of "mle" Objects</i> |
|-------------------|------------------------------------------------------|

Description

Extract of "mle" object

Objects from the Class

Objects can be created by calls of the form `new("summary.mle", ...)`, but most often by invoking `summary` on an "mle" object. They contain values meant for printing by `show`.

Slots

`call`: Object of class "language" The call that generated the "mle" object.

`coef`: Object of class "matrix". Estimated coefficients and standard errors

`m2logL`: Object of class "numeric". Minus twice the log likelihood.

Methods

show signature(object = "summary.mle"): Pretty-prints object

coef signature(object = "summary.mle"): Extracts the contents of the coef slot

See Also

[summary](#), [mle](#), [mle-class](#)

| | |
|----------------|------------------------------------------------------|
| update-methods | <i>Methods for Function update in Package stats4</i> |
|----------------|------------------------------------------------------|

Description

Update "mle" objects.

Usage

```
## S4 method for signature 'mle'
update(object, ..., evaluate = TRUE)
```

Arguments

| | |
|----------|------------------------------------------------------------------------------------------------------------------|
| object | An existing fit. |
| ... | Additional arguments to the call, or arguments with changed values. Use name = NULL to remove the argument name. |
| evaluate | If true evaluate the new call else return the call. |

Methods

signature(object = "ANY") Generic function: see [update](#).
signature(object = "mle") Update a fit.

Examples

```
x <- 0:10
y <- c(26, 17, 13, 12, 20, 5, 9, 8, 5, 4, 8)
ll <- function(ymax = 15, xhalf = 6)
  -sum(stats::dpois(y, lambda = ymax/(1+x/xhalf), log = TRUE))
fit <- mle(ll)
## note the recorded call contains ..1, a problem with S4 dispatch
update(fit, fixed = list(xhalf = 3))
```

| | |
|--------------|----------------------------------------------------|
| vcov-methods | <i>Methods for Function vcov in Package stats4</i> |
|--------------|----------------------------------------------------|

Description

Extract the approximate variance-covariance matrix from "mle" objects.

Methods

signature(object = "ANY") Generic function: see [vcov](#).
signature(object = "mle") Extract the estimated variance-covariance matrix for the estimated parameters (if any).

Chapter 12

The tcltk package

tcltk-package

Tcl/Tk Interface

Description

Interface and language bindings to Tcl/Tk GUI elements.

Details

This package provides access to the platform-independent Tcl scripting language and Tk GUI elements. See [TkWidgets](#) for a list of supported widgets, [TkWidgetcmds](#) for commands to work with them, and references in those files for more.

The Tcl/Tk documentation is in the system man pages.

For a complete list of functions, use `ls("package:tcltk")`.

Note that Tk will not be initialized if there is no `DISPLAY` variable set, but Tcl can still be used. This is most useful to allow the loading of a package which depends on **tcltk** in a session that does not actually use it (e.g., during installation).

Author(s)

R Core Team

Maintainer: R Core Team <R-core@r-project.org>

TclInterface

*Low-level Tcl/Tk Interface***Description**

These functions and variables provide the basic glue between R and the Tcl interpreter and Tk GUI toolkit. Tk windows may be represented via R objects. Tcl variables can be accessed via objects of class `tclVar` and the C level interface to Tcl objects is accessed via objects of class `tclObj`.

Usage

```
.Tcl(...)
.Tcl.objv(objv)
.Tcl.args(...)
.Tcl.args.objv(...)
.Tcl.callback(...)
.Tk.ID(win)
.Tk.newwin(ID)
.Tk.subwin(parent)
.TkRoot
.TkUp

tkdestroy(win)
is.tkwin(x)

tclObj(x) <- value
## S3 method for class 'tclVar'
tclObj(x)
## S3 replacement method for class 'tclVar'
tclObj(x) <- value

as.tclObj(x, drop = FALSE)
is.tclObj(x)

## S3 method for class 'tclObj'
as.character(x, ...)
## S3 method for class 'tclObj'
as.integer(x, ...)
## S3 method for class 'tclObj'
as.double(x, ...)
## S3 method for class 'tclObj'
as.logical(x, ...)
## S3 method for class 'tclObj'
as.raw(x, ...)
## S3 method for class 'tclObj'
tclvalue(x)

## Default S3 method:
tclvalue(x)
## Default S3 replacement method:
tclvalue(x) <- value

addTclPath(path = ".")
tclRequire(package, warn = TRUE)
tclVersion()

```

Arguments

| | |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <code>objv</code> | a named vector of Tcl objects |
| <code>win</code> | a window structure |
| <code>x</code> | an object |
| <code>i</code> | character or (unquoted) name |
| <code>drop</code> | logical. Indicates whether a single-element vector should be made into a simple Tcl object or a list of length one |
| <code>value</code> | For <code>tclvalue</code> assignments, a character string. For <code>tclObj</code> assignments, an object of class <code>tclObj</code> |

| | |
|---------|-----------------------------------------------------------|
| ID | a window ID |
| parent | a window which becomes the parent of the resulting window |
| path | path to a directory containing Tcl packages |
| package | a Tcl package name |
| warn | logical. Warn if not found? |
| ... | Additional arguments. See below. |
| init | initialization value |

Details

Many of these functions are not intended for general use but are used internally by the commands that create and manipulate Tk widgets and Tcl objects. At the lowest level `.Tcl` sends a command as a text string to the Tcl interpreter and returns the result as an object of class `tclObj` (see below). A newer variant `.Tcl.objv` accepts arguments in the form of a named list of `tclObj` objects.

`.Tcl.args` converts an R argument list of `tag = value` pairs to the Tcl `-option value` style, thus enabling a simple translation between the two languages. To send a value with no preceding option flag to Tcl, just use an untagged argument. In the rare case one needs an option with no subsequent value `tag = NULL` can be used. Most values are just converted to character mode and inserted in the command string, but window objects are passed using their ID string, and callbacks are passed via the result of `.Tcl.callback`. Tags are converted to option flags simply by prepending a `-`

`.Tcl.args.objv` serves a similar purpose as `.Tcl.args` but produces a list of `tclObj` objects suitable for passing to `.Tcl.objv`. The names of the list are converted to Tcl option style internally by `.Tcl.objv`.

Callbacks can be either *atomic callbacks* handled by `.Tcl.callback` or expressions. An expression is treated as a list of atomic callbacks, with the following exceptions: if an element is a name, it is first evaluated in the callers frame, and likewise if it is an explicit function definition; the `break` expression is translated directly to the Tcl counterpart. `.Tcl.callback` converts R functions and unevaluated calls to Tcl command strings. The argument must be either a function closure or an object of mode `"call"` followed by an environment. The return value in the first case is of the form `R_call 0x408b94d4` in which the hexadecimal number is the memory address of the function. In the second case it will be of the form `R_call_lang 0x8a95904 0x819bfd0`. For expressions, a sequence of similar items is generated, separated by semicolons. `.Tcl.args` takes special precautions to ensure that functions or calls will continue to exist at the specified address by assigning the callback into the relevant window environment (see below).

Tk windows are represented as objects of class `tkwin` which are lists containing a `ID` field and an `env` field which is an R environments, enclosed in the global environment. The value of the `ID` field is identical to the Tk window name. The `env` environment contains a `parent` variable and a `num.subwin` variable. If the window obtains sub-windows and callbacks, they are added as variables to the environment. `.TkRoot` is the top window with ID `"."`; this window is not displayed in order to avoid ill effects of closing it via window manager controls. The `parent` variable is undefined for `.TkRoot`.

`.Tk.ID` extracts the ID of a window, `.Tk.newwin` creates a new window environment with a given ID and `.Tk.subwin` creates a new window which is a sub-window of a given parent window.

`.TkUp` is a logical flag to indicate whether the Tk widget system is active; if `FALSE`, only the Tcl interpreter is available.

`tkdestroy` destroys a window and also removes the reference to a window from its parent.

`is.tkwin` can be used to test whether a given object is a window environment.

`tclVar` creates a new Tcl variable and initializes it to `init`. An R object of class `tclVar` is created to represent it. Using `as.character` on the object returns the Tcl variable name. Accessing the Tcl variable from R is done using the `tclvalue` function, which can also occur on the left-hand side of assignments. If `tclvalue` is passed an argument which is not a `tclVar` object, then it will assume that it is a character string explicitly naming global Tcl variable. Tcl variables created by `tclVar` are uniquely named and automatically unset by the garbage collector when the representing object is no longer in use.

`tclArray` creates a new Tcl array and initializes it to the empty array. An R object of class `tclArray` and inheriting from class `tclVar` is created to represent it. You can access elements of the Tcl array using indexing with `[[` or `$`, which also allow replacement forms. Notice that Tcl arrays are associative by nature and hence unordered; indexing with a numeric index `i` refers to the element with the *name* `as.character(i)`. Multiple indices are pasted together separated by commas to form a single name. You can query the length and the set of names in an array using methods for `length` and `names`, respectively; these cannot meaningfully be set so assignment forms exist only to print an error message.

It is possible to access Tcl's 'dual-ported' objects directly, thus avoiding parsing and deparsing of their string representation. This works by using objects of class `tclObj`. The string representation of such objects can be extracted (but not set) using `tclvalue` and conversion to vectors of mode `"character"`, `"double"`, `"integer"`, `"logical"`, and `"raw"` is performed using the standard coercion functions `as.character`, etc. Conversely, such vectors can be converted using `as.tclObj`. There is an ambiguity as to what should happen for length one vectors, controlled by the `drop` argument; there are cases where the distinction matters to Tcl, although mostly it treats them equivalently. Notice that `tclvalue` and `as.character` differ on an object whose string representation has embedded spaces, the former is sometimes to be preferred, in particular when applied to the result of `tclread`, `tkgetOpenFile`, and similar functions. The `as.raw` method returns a raw vector or a list of raw vectors and can be used to return binary data from Tcl.

The object behind a `tclVar` object is extracted using `tclObj(x)` which also allows an assignment form, in which the right hand side of the assignment is automatically converted using `as.tclObj`. There is a print method for `tclObj` objects; it prints `<Tcl>` followed by the string representation of the object. Notice that `as.character` on a `tclVar` object is the *name* of the corresponding Tcl variable and not the value.

Tcl packages can be loaded with `tclRequire`; it may be necessary to add the directory where they are found to the Tcl search path with `addTclPath`. The return value is a class `"tclObj"` object if it succeeds, or `FALSE` if it fails (when a warning is issued). To see the current search path as an R character vector, use:

```
strsplit(tclvalue('auto_path'), " ")[1]
```

The Tcl version (including patch level) is returned as a character string (such as `"8.6.3"`).

Note

Strings containing unbalanced braces are currently not handled well in many circumstances.

See Also

[TkWidgets](#), [TkCommands](#), [TkWidgetcmds](#).

[capabilities](#)("tcltk") to see if Tcl/Tk support was compiled into this build of R.

Examples

```
tclVersion()

.Tcl("format \"%s\n\" \"Hello, World!\n")

f <- function() cat("HI!\n")
.Tcl.callback(f)
.Tcl.args(text = "Push!", command = f) # NB: Different address

xyzy <- tclVar(7913)
tclvalue(xyzy)
tclvalue(xyzy) <- "foo"
as.character(xyzy)
tcl("set", as.character(xyzy))

## Not run:
## These cannot be run by example() but should be OK when pasted
## into an interactive R session with the tcltk package loaded
top <- tktoplevel() # a Tk widget, see Tk-widgets
ls(envir = top$env, all.names = TRUE)

## End(Not run)

ls(envir = .TkRoot$env, all.names = TRUE) # .Tcl.args put a callback ref in here
```

| | |
|----------------|-----------------------------------------------|
| tclServiceMode | <i>Allow Tcl events to be serviced or not</i> |
|----------------|-----------------------------------------------|

Description

This function controls or reports on the Tcl service mode, i.e., whether Tcl will respond to events.

Usage

```
tclServiceMode(on = NULL)
```

Arguments

on (logical) Whether event servicing is turned on.

Details

If called with on == NULL (the default), no change is made.

Note that this blocks all Tcl/Tk activity, including for widgets from other packages. It may be better to manage mapping of windows individually.

Value

The value of the Tcl service mode before the call.

Examples

```
## see demo(tkcanvas) for an example
oldmode <- tclServiceMode(FALSE)
# Do some work to create a nice picture.
# Nothing will be displayed until...
tclServiceMode(oldmode)
## another idea is to use tkwm.withdraw() ... tkwm.deiconify()
```

TkCommands

Tk non-widget commands

Description

These functions interface to Tk non-widget commands, such as the window manager interface commands and the geometry managers.

Usage

```
tcl(...)
tktitle(x)

tktitle(x) <- value

tkbell(...)
tkbind(...)
tkbindtags(...)
tkfocus(...)
tklower(...)
tkraise(...)

tkclipboard.append(...)
tkclipboard.clear(...)

tkevent.add(...)
tkevent.delete(...)
tkevent.generate(...)
tkevent.info(...)
```

```
tkfont.actual(...)
tkfont.configure(...)
tkfont.create(...)
tkfont.delete(...)
tkfont.families(...)
tkfont.measure(...)
tkfont.metrics(...)
tkfont.names(...)

tkgrab(...)
tkgrab.current(...)
tkgrab.release(...)
tkgrab.set(...)
tkgrab.status(...)

tkimage.create(...)
tkimage.delete(...)
tkimage.height(...)
tkimage.inuse(...)
tkimage.names(...)
tkimage.type(...)
tkimage.types(...)
tkimage.width(...)

## NB: some widgets also have a selection.clear command,
## hence the "X".

tkXselection.clear(...)
tkXselection.get(...)
tkXselection.handle(...)
tkXselection.own(...)

tkwait.variable(...)
tkwait.visibility(...)
tkwait.window(...)

## wininfo actually has a large number of subcommands,
## but it's rarely used,
## so use tkwininfo("atom", ...) etc. instead.

tclfile.dir(...)
tclopen(...)
tclclose(...)
tclputs(...)
tclread(...)
```

Arguments

| | |
|-------|----------------------------------------------|
| x | A window object |
| value | For tktitle assignments, a character string. |
| ... | Handled via <code>.Tcl.args</code> |

Details

tcl provides a generic interface to calling any Tk or Tcl command by simply running `.Tcl.args.objv` on the argument list and passing the result to `.Tcl.objv`. Most of the other commands simply call tcl with a particular first argument and sometimes also a second argument giving the subcommand.

tktitle and its assignment form provides an alternate interface to Tk's `wm title`

There are far too many of these commands to describe them and their arguments in full. Please refer to the Tcl/Tk documentation for details. With a few exceptions, the pattern is that Tk subcommands like `pack configure` are converted to function names like `tkpack.configure`, and Tcl subcommands are like `tclfile.dir`.

See Also

[TclInterface](#), [TkWidgets](#), [TkWidgetcmds](#)

Examples

```
## Not run:
```

```
## These cannot be run by examples() but should be OK when pasted
## into an interactive R session with the tcltk package loaded

tt <- tktoplevel()
tkpack(l1 <- tklabel(tt, text = "Heave"), l2 <- tklabel(tt, text = "Ho"))
tkpack.configure(l1, side = "left")

## Try stretching the window and then

tkdestroy(tt)

## End(Not run)
```

tkpager

Page file using Tk text widget

Description

This plugs into `file.show`, showing files in separate windows.

Usage

```
tkpager(file, header, title, delete.file)
```

Arguments

| | |
|--------------------------|-----------------------------------------------------------------------------------------------------|
| <code>file</code> | character vector containing the names of the files to be displayed |
| <code>header</code> | headers to use for each file |
| <code>title</code> | common title to use for the window(s). Pasted together with the header to form actual window title. |
| <code>delete.file</code> | logical. Should file(s) be deleted after display? |

Note

The `"\b_"` string used for underlining is currently quietly removed. The font and background colour are currently hardcoded to Courier and gray90.

See Also

[file.show](#)

tkProgressBar

*Progress Bars via Tk***Description**

Put up a Tk progress bar widget.

Usage

```
tkProgressBar(title = "R progress bar", label = "",
             min = 0, max = 1, initial = 0, width = 300)

getTkProgressBar(pb)
setTkProgressBar(pb, value, title = NULL, label = NULL)
## S3 method for class 'tkProgressBar'
close(con, ...)
```

Arguments

| | |
|----------------|-----------------------------------------------------------------------------------------------|
| title, label | character strings, giving the window title and the label on the dialog box respectively. |
| min, max | (finite) numeric values for the extremes of the progress bar. |
| initial, value | initial or new value for the progress bar. |
| width | the width of the progress bar in pixels: the dialog box will be 40 pixels wider (plus frame). |
| pb, con | an object of class "tkProgressBar". |
| ... | for consistency with the generic. |

Details

tkProgressBar will display a widget containing a label and progress bar.

setTkProgressBar will update the value and for non-NULL values, the title and label (provided there was one when the widget was created). Missing (NA) and out-of-range values of value will be (silently) ignored.

The progress bar should be closed when finished with.

This will use the ttk::progressbar widget for Tk version 8.5 or later, otherwise R's copy of BWidget's progressbar.

Value

For tkProgressBar an object of class "tkProgressBar".

For getTkProgressBar and setTkProgressBar, a length-one numeric vector giving the previous value (invisibly for setTkProgressBar).

See Also[txtProgressBar](#)**Examples**

```

pb <- tkProgressBar("test progress bar", "Some information in %",
                    0, 100, 50)
Sys.sleep(0.5)
u <- c(0, sort(runif(20, 0, 100)), 100)
for(i in u) {
  Sys.sleep(0.1)
  info <- sprintf("%d%% done", round(i))
  setTkProgressBar(pb, i, sprintf("test (%s)", info), info)
}
Sys.sleep(5)
close(pb)

```

tkStartGUI

*Tcl/Tk GUI startup***Description**

Starts up the Tcl/Tk GUI

Usage

```
tkStartGUI()
```

Details

Starts a GUI console implemented via a Tk text widget. This should probably be called at most once per session. Also redefines the file pager (as used by `help()`) to be the Tk pager.

Note

`tkStartGUI()` saves its evaluation environment as `.GUIenv`. This means that the user interface elements can be accessed in order to extend the interface. The three main objects are named `Term`, `Menu`, and `Toolbar`, and the various submenus and callback functions can be seen with `ls(envir = .GUIenv)`.

TkWidgetcmds

Tk widget commands

Description

These functions interface to Tk widget commands.

Usage

```
tkactivate(widget, ...)
tkadd(widget, ...)
tkaddtag(widget, ...)
tkbbox(widget, ...)
tkcanvasx(widget, ...)
tkcanvasy(widget, ...)
tkcget(widget, ...)
tkcompare(widget, ...)
tkconfigure(widget, ...)
tkcoords(widget, ...)
tkcreate(widget, ...)
tkcurselection(widget, ...)
tkdchars(widget, ...)
tkdebug(widget, ...)
tkdelete(widget, ...)
tkdelta(widget, ...)
tkdeselect(widget, ...)
tkdlineinfo(widget, ...)
tkdtag(widget, ...)
tkdump(widget, ...)
tkentrycget(widget, ...)
tkentryconfigure(widget, ...)
tkfind(widget, ...)
tkflash(widget, ...)
tkfraction(widget, ...)
tkget(widget, ...)
tkgettags(widget, ...)
tkicursor(widget, ...)
tkidentify(widget, ...)
tkindex(widget, ...)
tkinsert(widget, ...)
tkinvoke(widget, ...)
tkitembind(widget, ...)
tkitemcget(widget, ...)
tkitemconfigure(widget, ...)
tkitemfocus(widget, ...)
tkitemlower(widget, ...)
tkitemraise(widget, ...)
```

```
tkitemscale(widget, ...)
tkmark.gravity(widget, ...)
tkmark.names(widget, ...)
tkmark.next(widget, ...)
tkmark.previous(widget, ...)
tkmark.set(widget, ...)
tkmark.unset(widget, ...)
tkmove(widget, ...)
tknearest(widget, ...)
tkpost(widget, ...)
tkpostcascade(widget, ...)
tkpostscript(widget, ...)
tkscan.mark(widget, ...)
tkscan.dragto(widget, ...)
tksearch(widget, ...)
tksee(widget, ...)
tkselect(widget, ...)
tkselection.adjust(widget, ...)
tkselection.anchor(widget, ...)
tkselection.clear(widget, ...)
tkselection.from(widget, ...)
tkselection.includes(widget, ...)
tkselection.present(widget, ...)
tkselection.range(widget, ...)
tkselection.set(widget, ...)
tkselection.to(widget, ...)
tkset(widget, ...)
tksize(widget, ...)
tktoggle(widget, ...)
tktag.add(widget, ...)
tktag.bind(widget, ...)
tktag.cget(widget, ...)
tktag.configure(widget, ...)
tktag.delete(widget, ...)
tktag.lower(widget, ...)
tktag.names(widget, ...)
tktag.nextrange(widget, ...)
tktag.prevrange(widget, ...)
tktag.raise(widget, ...)
tktag.ranges(widget, ...)
tktag.remove(widget, ...)
tktype(widget, ...)
tkunpost(widget, ...)
tkwindow.cget(widget, ...)
tkwindow.configure(widget, ...)
tkwindow.create(widget, ...)
tkwindow.names(widget, ...)
tkxview(widget, ...)
```

```

tkxview.moveto(widget, ...)
tkxview.scroll(widget, ...)
tkyposition(widget, ...)
tkyview(widget, ...)
tkyview.moveto(widget, ...)
tkyview.scroll(widget, ...)

```

Arguments

| | |
|--------|------------------------------------|
| widget | The widget this applies to |
| ... | Handled via <code>.Tcl.args</code> |

Details

There are far too many of these commands to describe them and their arguments in full. Please refer to the Tcl/Tk documentation for details. Except for a few exceptions, the pattern is that Tcl widget commands possibly with subcommands like `.a.b selection clear` are converted to function names like `tkselection.clear` and the widget is given as the first argument.

Examples

```

## Not run:
## These cannot be run by examples() but should be OK when pasted
## into an interactive R session with the tcltk package loaded

tt <- tkoplevel()
tkpack(txt.w <- tktext(tt))
tkinsert(txt.w, "0.0", "plot(1:10)")

# callback function
eval.txt <- function() eval(str2lang(tclvalue(tkget(txt.w, "0.0", "end"))))
tkpack(but.w <- tkbutton(tt, text = "Submit", command = eval.txt))

## Try pressing the button, edit the text and when finished:

tkdestroy(tt)

## End(Not run)

```

Description

Create Tk widgets and associated R objects.

Usage

```
tkwidget(parent, type, ...)

tkbutton(parent, ...)
tkcanvas(parent, ...)
tkcheckboxbutton(parent, ...)
tkentry(parent, ...)
ttkentry(parent, ...)
tkframe(parent, ...)
tklabel(parent, ...)
tklistbox(parent, ...)
tkmenu(parent, ...)
tkmenubutton(parent, ...)
tkmessage(parent, ...)
tkradiobutton(parent, ...)
tkscale(parent, ...)
tkscrollbar(parent, ...)
tktext(parent, ...)
tktoplevel(parent = .TkRoot, ...)

ttkbutton(parent, ...)
ttkcheckboxbutton(parent, ...)
ttkcombobox(parent, ...)
ttkframe(parent, ...)
ttklabel(parent, ...)
ttklabelframe(parent, ...)
ttkmenubutton(parent, ...)
ttknotebook(parent, ...)
ttkpanedwindow(parent, ...)
ttkprogressbar(parent, ...)
ttkradiobutton(parent, ...)
ttkscale(parent, ...)
ttkscrollbar(parent, ...)
ttkseparator(parent, ...)
ttksizegrip(parent, ...)
ttkspinbox(parent, ...)
ttktreeview(parent, ...)
```

Arguments

| | |
|--------|-----------------------------------------------|
| parent | Parent of widget window. |
| type | string describing the type of widget desired. |
| ... | handled via .Tcl.args . |

Details

These functions create Tk widgets. `tkwidget` creates a widget of a given type, the others simply call `tkwidget` with the respective type argument.

The functions starting `ttk` are for the themed widget set for Tk 8.5 or later. A tutorial can be found at <https://tkdocs.com/>.

It is not possible to describe the widgets and their arguments in full. Please refer to the Tcl/Tk documentation.

[TclInterface](#), [TkCommands](#), [TkWidgetcmds](#)

Examples

```
## Not run:
## These cannot be run by examples() but should be OK when pasted
## into an interactive R session with the tcltk package loaded

tt <- tktoplevel()
label.widget <- tklabel(tt, text = "Hello, World!")
button.widget <- tkbutton(tt, text = "Push",
                          command = function()cat("OW!\n"))
tkpack(label.widget, button.widget) # geometry manager
                                   # see Tk-commands

## Push the button and then...

tkdestroy(tt)

## test for themed widgets
if(as.character(tcl("info", "tclversion")) >= "8.5") {
  # make use of themed widgets
  # list themes
  themes <- as.character(tcl("ttk::style", "theme", "names"))
  themes
  # select a theme -- for pre-XP windows
  # tcl("ttk::style", "theme", "use", "winnative")
  tcl("ttk::style", "theme", "use", themes[1])
} else {
  # use Tk 8.0 widgets
}

## End(Not run)
```

| | |
|---------------|--------------------------------------|
| tk_choose.dir | <i>Choose a Folder Interactively</i> |
|---------------|--------------------------------------|

Description

Use a Tk widget to choose a directory interactively.

Usage

```
tk_choose.dir(default = "", caption = "Select directory")
```

Arguments

| | |
|---------|--------------------------------------|
| default | which directory to show initially. |
| caption | the caption on the selection dialog. |

Value

A length-one character vector, character NA if ‘Cancel’ was selected.

See Also

[tk_choose.files](#)

Examples

```
if (interactive()) tk_choose.dir(getwd(), "Choose a suitable folder")
```

| | |
|-----------------|---------------------------------------------|
| tk_choose.files | <i>Choose a List of Files Interactively</i> |
|-----------------|---------------------------------------------|

Description

Use a Tk file dialog to choose a list of zero or more files interactively.

Usage

```
tk_choose.files(default = "", caption = "Select files",  
                multi = TRUE, filters = NULL, index = 1)
```

Arguments

| | |
|---------|--------------------------------------------------|
| default | which filename to show initially. |
| caption | the caption on the file selection dialog. |
| multi | whether to allow multiple files to be selected. |
| filters | two-column character matrix of filename filters. |
| index | unused. |

Details

Unlike `file.choose`, `tk_choose.files` will always attempt to return a character vector giving a list of files. If the user cancels the dialog, then zero files are returned, whereas `file.choose` would signal an error.

The format of filters can be seen from the example. File patterns are specified via extensions, with "*" meaning any file, and "" any file without an extension (a filename not containing a period). (Other forms may work on specific platforms.) Note that the way to have multiple extensions for one file type is to have multiple rows with the same name in the first column, and that whether the extensions are named in file chooser widget is platform-specific. **The format may change before release.**

Value

A character vector giving zero or more file paths.

Note

A bug in Tk 8.5.0–8.5.4 prevented multiple selections being used.

See Also

`file.choose`, `tk_choose.dir`

Examples

```
Filters <- matrix(c("R code", ".R", "R code", ".s",
                  "Text", ".txt", "All files", "*"),
                 4, 2, byrow = TRUE)

Filters
if(interactive()) tk_choose.files(filter = Filters)
```

tk_messageBox

Tk Message Box

Description

An implementation of a generic message box using Tk.

Usage

```
tk_messageBox(type = c("ok", "okcancel", "yesno", "yesnocancel",
                      "retrycancel", "abortretryignore"),
             message, caption = "", default = "", ...)
```

Arguments

| | |
|---------|----------------------------------------------------------------------------------------------------------|
| type | character. The type of dialog box. It will have the buttons implied by its name. Can be abbreviated. |
| message | character. The information field of the dialog box. |
| caption | the caption on the widget displayed. |
| default | character. The name of the button to be used as the default. |
| ... | additional named arguments to be passed to the Tk function of this name. An example is icon = "warning". |

Value

A character string giving the name of the button pressed.

See Also

[tkmessageBox](#) for a 'raw' interface.

| | |
|----------------|---------------------------------|
| tk_select.list | <i>Select Items from a List</i> |
|----------------|---------------------------------|

Description

Select item(s) from a character vector using a Tk listbox.

Usage

```
tk_select.list(choices, preselect = NULL, multiple = FALSE,
               title = NULL)
```

Arguments

| | |
|-----------|-----------------------------------------------------------------------------------------------------------------------|
| choices | a character vector of items. |
| preselect | a character vector, or NULL. If non-null and if the string(s) appear in the list, the item(s) are selected initially. |
| multiple | logical: can more than one item be selected? |
| title | optional character string for window title, or NULL for no title. |

Details

This is a version of [select.list](#) implemented as a Tk list box plus OK and Cancel buttons. There will be a scrollbar if the list is too long to fit comfortably on the screen.

The dialog box is *modal*, so a selection must be made or cancelled before the R session can proceed. Double-clicking on an item is equivalent to selecting it and then clicking OK.

If Tk is version 8.5 or later, themed widgets will be used.

Value

A character vector of selected items. If `multiple` is false and no item was selected (or Cancel was used), "" is returned. If `multiple` is true and no item was selected (or Cancel was used) then a character vector of length 0 is returned.

See Also

[select.list](#) (a text version except on Windows and the macOS GUI), [menu](#) (whose `graphics = TRUE` mode uses this on most Unix-alikes).

Chapter 13

The tools package

| | |
|---------------|--------------------------------------|
| tools-package | <i>Tools for Package Development</i> |
|---------------|--------------------------------------|

Description

Tools for package development, administration and documentation.

Details

This package contains tools for manipulating R packages and their documentation.

For a complete list of functions, use `library(help = "tools")`.

Author(s)

Kurt Hornik and Friedrich Leisch

Maintainer: R Core Team <R-core@r-project.org>

| | |
|-------------------|---------------------------|
| .print.via.format | <i>Printing Utilities</i> |
|-------------------|---------------------------|

Description

`.print.via.format` is a “prototype” `print()` method, useful, at least as a start, by a simple

```
print.<myS3class> <- .print.via.format
```

Usage

```
.print.via.format(x, ...)
```

Arguments

`x` object to be printed.

`...` optional further arguments, passed to `format`.

Value

`x`, invisibly (by `invisible()`), as `print` methods should.

See Also

The `print` generic; its default method `print.default` (used for many basic implicit classes such as "numeric", "character" and arrays of them, `lists` etc).

Examples

```
## The function is simply defined as
function (x, ...) {
  writeLines(format(x, ...))
  invisible(x)
}
```

is used for simple print methods in R, and as prototype for new methods.

| | |
|--------------|--------------------------------------------------|
| add_datalist | <i>Add a 'datalist' File to a Source Package</i> |
|--------------|--------------------------------------------------|

Description

The `data()` command with no arguments lists all the datasets available via data in attached packages, and to do so a per-package list is installed. Creating that list at install time can be slow for packages with huge datasets, and can be expedited by a supplying 'data/datalist' file.

Usage

```
add_datalist(pkgpath, force = FALSE, small.size = 1024^2)
```

Arguments

`pkgpath` The path to a (source) package.

`force` logical: can an existing 'data/datalist' file be over-written?

`small.size` number: a 'data/datalist' file is created only if the total size of the data files is larger than `small.size` bytes.

Details

R CMD build will call this function to add a data list to packages with 1MB or more of file in the ‘data’ directory.

It can also be also helpful to give a ‘data/datalist’ file in packages whose datasets have many dependencies, including loading the packages itself (and maybe others).

| | |
|-----------------|-----------------------------------|
| assertCondition | <i>Asserting Error Conditions</i> |
|-----------------|-----------------------------------|

Description

When testing code, it is not sufficient to check that results are correct, but also that errors or warnings are signalled in appropriate situations. The functions described here provide a convenient facility for doing so. The three functions check that evaluating the supplied expression produces an error, a warning or one of a specified list of conditions, respectively. If the assertion fails, an error is signalled.

Usage

```
assertError(expr, classes = "error", verbose = FALSE)
assertWarning(expr, classes = "warning", verbose = FALSE)
assertCondition(expr, ..., .exprString = , verbose = FALSE)
```

Arguments

| | |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| expr | an unevaluated R expression which will be evaluated via tryCatch (expr, ...). |
| classes, ... | character strings corresponding to the classes of the conditions that would satisfy the assertion; e.g., "error" or "warning". If none are specified, any condition will satisfy the assertion. See the details section. |
| .exprString | The string to be printed corresponding to expr. By default, the actual expr will be deparsed. Will be omitted if the function is supplied with the actual expression to be tested. If assertCondition() is called from another function, with the actual expression passed as an argument to that function, supply the deparsed version. |
| verbose | If TRUE, a message is printed when the condition is satisfied. |

Details

assertCondition() uses the general condition mechanism to check all the conditions generated in evaluating expr. The occurrence of any of the supplied condition classes among these satisfies the assertion regardless of what other conditions may be signalled.

assertError() is a convenience function for asserting errors; it calls assertCondition().

assertWarning() asserts that a warning will be signalled, but *not* an error, whereas assertCondition(expr, "warning") will be satisfied even if an error follows the warning. See the examples.

Value

If the assertion is satisfied, a list of all the condition objects signalled is returned, invisibly. See [conditionMessage](#) for the interpretation of these objects. Note that *all* conditions signalled during the evaluation are returned, whether or not they were among the requirements.

Author(s)

John Chambers and Martin Maechler

See Also

[stop](#), [warning](#); [signalCondition](#), [tryCatch](#).

Examples

```
assertError(sqrt("abc"))
assertWarning(matrix(1:8, 4,3))

assertCondition( ""-1 ) # ok, any condition would satisfy this

try( assertCondition(sqrt(2), "warning") )
## .. Failed to get warning in evaluating sqrt(2)
  assertCondition(sqrt("abc"), "error") # ok
try( assertCondition(sqrt("abc"), "warning") )# -> error: had no warning
  assertCondition(sqrt("abc"), "error")
## identical to assertError() call above

assertCondition(matrix(1:5, 2,3), "warning")
try( assertCondition(matrix(1:8, 4,3), "error") )
## .. Failed to get expected error ....

## either warning or worse:
assertCondition(matrix(1:8, 4,3), "error","warning") # OK
assertCondition(matrix(1:8, 4, 3), "warning") # OK

## when both are signalled:
ff <- function() { warning("my warning"); stop("my error") }
  assertCondition(ff(), "warning")
## but assertWarning does not allow an error to follow
try(assertWarning(ff()))
```

```

    assertCondition(ff(), "error")          # ok
assertCondition(ff(), "error", "warning") # ok (quietly, catching warning)

## assert that assertC..() does not assert [and use *one* argument only]
assertCondition( assertCondition(sqrt( 2  ), "warning") )
assertCondition( assertCondition(sqrt("abc"), "warning"), "error")
assertCondition( assertCondition(matrix(1:8, 4,3), "error"),
                  "error")

```

bibstyle

Select or Define a Bibliography Style

Description

This function defines and registers styles for rendering **bibentry** objects into ‘Rd’ format, for later conversion to text, HTML, etc.

Usage

```

bibstyle(style, envir, ..., .init = FALSE, .default = TRUE)
getBibstyle(all = FALSE)

```

Arguments

| | |
|-----------------------|-------------------------------------------------------------------------|
| <code>style</code> | A character string naming the style. |
| <code>envir</code> | (optional) An environment holding the functions to implement the style. |
| <code>...</code> | Named arguments to add to the environment. |
| <code>.init</code> | Whether to initialize the environment from the default style "JSS". |
| <code>.default</code> | Whether to set the specified style as the default style. |
| <code>all</code> | Whether to return the names of all registered styles. |

Details

Rendering of **bibentry** objects may be done using routines modelled after those used by BibTeX. This function allows environments to be created and manipulated to contain those routines.

There are two ways to create a new style environment. The easiest is to set `.init = TRUE`, in which case the environment will be initialized with a copy of the default "JSS" environment. (This style is modelled after the ‘jss.bst’ style used by the *Journal of Statistical Software*.) Alternatively, the `envir` argument can be used to specify a completely new style environment.

To find the name of the default style, use `getBibstyle()`. To retrieve an existing style without setting it as the default, use `bibstyle(style, .default = FALSE)`. To modify an existing style, specify style and some named entries via `...` (Modifying the default "JSS" style is discouraged.) Setting style to NULL or leaving it missing will retrieve the default style, but modifications will not be allowed.

At a minimum, the environment should contain routines to render each of the 12 types of bibliographic entry supported by `bibentry` as well as several other routines described below. The former must be named `formatArticle`, `formatBook`, `formatInbook`, `formatIncollection`, `formatInproceedings`, `formatManual`, `formatMastersthesis`, `formatMisc`, `formatPhdthesis`, `formatProceedings`, `formatTechreport` and `formatUnpublished`. Each of these takes one argument, a single `unclass`'ed entry from the `bibentry` vector passed to the renderer, and should produce a single element character vector (possibly containing newlines).

The other routines are as follows. `sortKeys`, a function to produce a sort key to sort the entries, is passed the original `bibentry` vector and should produce a sortable vector of the same length to define the sort order. Finally, the optional function `cite` should have the same argument list as `utils::cite`, and should produce a citation to be used in text.

The `format` method for "bibentry" objects adds a field named `".index"` to each entry after sorting and before formatting. This is a 1-based index within the complete object that can be used in styles that require numbering. Although the "JSS" style doesn't use numbers, it includes a `fmtPrefix()` stub function that may be used to display them. See the example below.

Value

`bibstyle` returns the environment which has been selected or created.

`getBibstyle` returns the name of the default style, or all style names.

  address = "Vienna, Austria",
  year = 2013,
  url = "https://www.R-project.org"),
  bibentry(bibtype = "article",
    author = c(person(c("George", "E.", "P."), "Box"),
      person(c("David", "R."), "Cox")),
    year = 1964,
    title = "An Analysis of Transformations",
    journal = "Journal of the Royal Statistical Society, Series B",
    volume = 26, number = 2, pages = "211--243",
    doi = "10.1111/j.2517-6161.1964.tb00553.x"))

bibstyle("unsorted", sortKeys = function(refs) seq_along(refs),
```

```

    fmtPrefix = function(paper) paste0("[", paper$.index, "]"),
    .init = TRUE)
print(refs, .bibstyle = "unsorted")

```

buildVignette

Build One Vignette

Description

Run [Sweave](#) (or other custom weave function), [texi2pdf](#), and/or [Stangle](#) (or other custom tangle function) on one vignette.

This is the workhorse of R CMD Sweave.

Usage

```

buildVignette(file, dir = ".", weave = TRUE, latex = TRUE, tangle = TRUE,
              quiet = TRUE, clean = TRUE, keep = character(),
              engine = NULL, buildPkg = NULL, encoding, ...)

```

Arguments

| | |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| file | character; the vignette source file. |
| dir | character; the working directory in which the intermediate and output files will be produced. |
| weave | logical; should weave be run? |
| latex | logical; should texi2pdf be run if weaving produces a ‘.tex’ file? |
| tangle | logical; should tangle be run? |
| quiet | logical; run in quiet mode? |
| clean | logical; whether to remove some newly created, often intermediate, files. See details below. |
| keep | a list of file names to keep in any case when cleaning. Note that “target” files are kept anyway. |
| engine | NULL or character; name of vignette engine to use. Overrides any ‘\VignetteEngine{’ markup in the vignette. |
| buildPkg | NULL or a character vector; optional packages in which to find the vignette engine. |
| encoding | the encoding to assume for the file. If not specified, it will be read if possible from the file’s contents. Note that if the vignette is part of a package, buildVignettes reads the package’s encoding from the ‘DESCRIPTION’ file but this function does not. |
| ... | Additional arguments passed to weave and tangle. |

Details

This function determines the vignette engine for the vignette (default `utils::Sweave`), then weaves and/or tangles the vignette using that engine. Finally, if `clean` is `TRUE`, newly created intermediate files (non “targets”, where these depend on the engine, etc, and not any in `keep`) will be deleted. If `clean` is `NA`, and `weave` is `true`, newly created intermediate output files (e.g., ‘.tex’) will not be deleted even if a ‘.pdf’ file has been produced from them.

If `buildPkg` is specified, those packages will be loaded before the vignette is processed and will be used as the default packages in the search for a vignette engine, but an explicitly specified package in the vignette source (e.g., using ‘`\VignetteEngine{utils::Sweave}`’ to specify the Sweave engine in the **utils** package) will override it. In contrast, if the `engine` argument is given, it will override the vignette source.

Value

A character vector naming the files that have been produced.

[buildVignettes](#) for building all vignettes in a package.

| | |
|----------------|-----------------------------------------|
| buildVignettes | <i>List and Build Package Vignettes</i> |
|----------------|-----------------------------------------|

Description

Run [Sweave](#) (or other custom weave function) and [texi2pdf](#) on all vignettes of a package, or list the vignettes.

Usage

```
buildVignettes(package, dir, lib.loc = NULL, quiet = TRUE,  
               clean = TRUE, tangle = FALSE, skip = NULL,  
               ser_elibs = NULL)
```

```
pkgVignettes(package, dir, subdirs = NULL, lib.loc = NULL,  
              output = FALSE, source = FALSE, check = FALSE)
```

Arguments

| | |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| package | a character string naming an installed package. If given, vignette source files are by default looked for in subdirectory 'doc'. |
| dir | a character string specifying the path to a package's root source directory. If given, vignette source files are by default looked for in subdirectory 'vignettes'. |
| lib.loc | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package. |
| quiet | logical. Weave and run texi2pdf in quiet mode. |
| clean | Remove all files generated by the build, even if there were copies there before. |
| tangle | logical. Do tangling as well as weaving. |
| skip | a character vector of names of vignettes (without file extension, matching the names returned from <code>pkgVignettes</code>) which should be skipped, or TRUE to skip those with unavailable ' <code>\VignetteDepends</code> ' (from vignetteInfo). |
| ser_elibs | For use from R CMD check. |
| subdirs | a character vector of subdirectories of <code>dir</code> in which to look for vignettes. The first which exists is used. Defaults to "doc" if package is supplied, otherwise "vignettes". |
| output | logical indicating if the output filenames for each vignette should be returned (in component outputs). |
| source | logical indicating if the <i>tangled</i> output filenames for each vignette should be returned (in component sources). |
| check | logical. If TRUE, check whether all files that have vignette-like filenames have an identifiable vignette engine. This may be a false positive if a file is not a vignette but has a filename matching a pattern defined by one of the vignette engines. |

Details

`buildVignettes` is used by R CMD build and R CMD check to (re-)build vignette outputs from their sources.

As from R 3.4.1, both of these functions ignore files that are listed in the '`.Rbuildignore`' file in `dir`.

Value

`buildVignettes` is called for its side effect of creating the outputs of all vignettes, and if `tangle = TRUE`, extracting the R code.

`pkgVignettes` returns an object of class "pkgVignettes" if a vignette directory is found, otherwise NULL.

Examples

```
gVigns <- pkgVignettes("grid")
str(gVigns)
```

Description

charset_to_Unicode is a matrix of Unicode code points with columns for the common 8-bit encodings.

Adobe_glyphs is a data frame which gives Adobe glyph names for Unicode code points. It has two character columns, "adobe" and "unicode" (a 4-digit hex representation).

Usage

charset_to_Unicode

Adobe_glyphs

Details

charset_to_Unicode is an integer matrix of class `c("noquote", "hexmode")` so prints in hexadecimal. The mappings are those used by libiconv: there are differences in the way quotes and minus/hyphen are mapped between sources (and the postscript encoding files use a different mapping).

Adobe_glyphs includes all the Adobe glyph names which correspond to single Unicode characters. It is sorted by Unicode code point and within a point alphabetically on the glyph (there can be more than one name for a Unicode code point). The data are in the file '[R_HOME/share/encodings/Adobe_glyphlist](#)'.

Examples

```
## find Adobe names for ISOLatin2 chars.
latin2 <- charset_to_Unicode[, "ISOLatin2"]
aUnicode <- as.hexmode(paste0("0x", Adobe_glyphs$unicode))
keep <- aUnicode %in% latin2
aUnicode <- aUnicode[keep]
aAdobe <- Adobe_glyphs[keep, 1]
## first match
aLatin2 <- aAdobe[match(latin2, aUnicode)]
## all matches
bLatin2 <- lapply(1:256, function(x) aAdobe[aUnicode == latin2[x]])
format(bLatin2, justify = "none")
```

checkFF*Check Foreign Function Calls*

Description

Performs checks on calls to compiled code from R code. Currently only checks whether the interface functions such as `.C` and `.Fortran` are called with a `"NativeSymbolInfo"` first argument or with argument `PACKAGE` specified, which is highly recommended to avoid name clashes in foreign function calls.

Usage

```
checkFF(package, dir, file, lib.loc = NULL,
        registration = FALSE, check_DUP = FALSE,
        verbose = getOption("verbose"))
```

Arguments

| | |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>package</code> | a character string naming an installed package. If given, the installed R code of the package is checked. |
| <code>dir</code> | a character string specifying the path to a package's root source directory. This should contain the subdirectory 'R' (for R code). Only used if <code>package</code> is not given. |
| <code>file</code> | the name of a file containing R code to be checked. Used if neither <code>package</code> nor <code>dir</code> are given. |
| <code>lib.loc</code> | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. The specified library trees are used to search for package. |
| <code>registration</code> | a logical. If <code>TRUE</code> , checks the registration information on the call (if available). |
| <code>check_DUP</code> | a logical. If <code>TRUE</code> , <code>.C</code> and <code>.Fortran</code> calls with <code>DUP = FALSE</code> are reported. |
| <code>verbose</code> | a logical. If <code>TRUE</code> , additional diagnostics are printed (and the result is returned invisibly). |

Details

Note that we can only check if the name argument is a symbol or a character string, not what class of object the symbol resolves to at run-time.

If the package has a namespace which contains a `useDynLib` directive, calls in top-level functions in the package are not reported as their symbols will be preferentially looked up in the DLL named in the first `useDynLib` directive.

This checks that calls with `PACKAGE` specified are to the same package, and reports separately those which are in base packages and those which are in other packages (and if those packages are specified in the 'DESCRIPTION' file).

Value

An object of class "checkFF".

There are `format` and `print` methods to display the information contained in such objects.

See Also

`.C`, `.Fortran`; `Foreign`.

Examples

```
# order is pretty much random
checkFF(package = "stats", verbose = TRUE)
```

`checkMD5sums`*Check and Create MD5 Checksum Files*

Description

`checkMD5sums` checks the files against a file 'MD5'.

Usage

```
checkMD5sums(package, dir)
```

Arguments

| | |
|----------------------|--------------------------------------------------------------|
| <code>package</code> | the name of an installed package |
| <code>dir</code> | the path to the top-level directory of an installed package. |

Details

The file 'MD5' which is created is in a format which can be checked by `md5sum -c MD5` if a suitable command-line version of `md5sum` is available. (For Windows, one is supplied in the bundle at <https://cran.r-project.org/bin/windows/Rtools/>.)

If `dir` is missing, an installed package of name `package` is searched for.

The private function `tools:::.installMD5sums` is used to create MD5 files in the Windows build.

Value

`checkMD5sums` returns a logical, NA if there is no 'MD5' file to be checked.

See Also

`md5sum`

checkPoFiles

*Check Translation Files for Inconsistent Format Strings***Description**

These functions compare formats embedded in English messages with translated strings to check for consistency. `checkPoFile` checks one file, while `checkPoFiles` checks all files for specified or all languages.

Usage

```
checkPoFile(f, strictPlural = FALSE)
checkPoFiles(language, dir = ".")
```

Arguments

| | |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>f</code> | a character string giving a single filepath. |
| <code>strictPlural</code> | whether to compare formats of singular and plural forms in a strict way. |
| <code>language</code> | a character string giving a language code, or a ‘regexp’ (regular expression), to match languages in <code>dir</code> . Use <code>""</code> to denote all languages in the <code>dir</code> path. |
| <code>dir</code> | a path to a directory in which to check files. |

Details

Part of R’s internationalization depends on translations of messages in ‘.po’ files. In these files an ‘English’ message taken from the R sources is followed by a translation into another language. Many of these messages are format strings for C or R [sprintf](#) and related functions. In these cases, the translation must give a compatible format or an error will be generated when the message is displayed.

The rules for compatibility differ between C and R in several ways. C supports several conversions not supported by R, namely `c`, `u`, `p`, `n`. It is allowed in C’s `sprintf()` function to have more arguments than are needed by the format string, but in R the counts must match exactly. R requires types of arguments to match, whereas C will do the display whether it makes sense or not.

These functions compromise on the testing as follows. The additional formats allowed in C are accepted, and all differences in argument type or count are reported. As a consequence some reported differences are not errors.

If the `strictPlural` argument is `TRUE`, then argument lists must agree exactly between singular and plural forms of messages; if `FALSE`, then translations only need to match one or the other of the two forms. When `checkPoFiles` calls `checkPoFile`, the `strictPlural` argument is set to `TRUE` for files with names starting ‘R-’, and to `FALSE` otherwise.

Items marked as ‘fuzzy’ in the ‘.po’ file are not processed (as they are ignored by the message compiler).

If a difference is found, the translated string is checked for variant percent signs (e.g., the wide percent sign `"\uFF05"`). Such signs will not be recognized as format specifiers, and are likely to be errors.

Value

Both functions return an object of S3 class "check_po_files". A print method is defined for this class to display a report on the differences.

Author(s)

Duncan Murdoch

References

See the GNU gettext manual for the '.po' file format:

## End(Not run)
```

checkRd

Check an Rd Object

Description

Check an help file or the output of the [parse_Rd](#) function.

Usage

```
checkRd(Rd, defines = .Platform$OS.type, stages = "render",
        unknownOK = TRUE, listOK = TRUE, ..., def_enc = FALSE)
```

Arguments

| | |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------|
| Rd | a filename or Rd object to use as input. |
| defines | string(s) to use in #ifdef tests. |
| stages | at which stage ("build", "install", or "render") should \Sexpr macros be executed? See the notes below. |
| unknownOK | unrecognized macros are treated as errors if FALSE, otherwise warnings. |
| listOK | unnecessary non-empty braces (e.g., around text, not as an argument) are treated as errors if FALSE, otherwise warnings ("Lost braces"). |

... additional parameters to pass to `parse_Rd` when Rd is a filename. One that is often useful is encoding.

`def_enc` logical: has the package declared an encoding, so tests for non-ASCII text are suppressed?

Details

`checkRd` performs consistency checks on an Rd file, confirming that required sections are present, etc.

It accepts a filename for an Rd file, and will use `parse_Rd` to parse it before applying the checks. If so, warnings from `parse_Rd` are collected, together with those from the internal function `prepare_Rd`, which does the `#ifdef` and `\Sexpr` processing, drops sections that would not be rendered or are duplicated (and should not be) and removes empty sections.

An Rd object is passed through `prepare_Rd`, but it may already have been (and installed Rd objects have).

Warnings are given a ‘level’: those from `prepare_Rd` have level 0. These include

```
\Sexpr expects R code; found ...
Unprocessed ‘stage’ macro from stage-stage \Sexpr
All text must be in a section
Only one tag name section is allowed: the first will be used
docType type is unrecognized
Section name is unrecognized and will be dropped
Dropping empty section name
```

`checkRd` itself can show

```
7 Tag tag name not recognized
7 Unrecognized format: ...
7 \tabular format must be simple text
7 Unrecognized \tabular format: ...
7 Only n columns allowed in this table
7 Tag tag name is invalid in a block name block
7 \method not valid outside a code block
7 Tag \method is only valid in \usage
7 Tag \dontrun is only valid in \examples
7 Invalid email address: ...
7 Invalid URL: ...
5 \name should not contain !, | or @
5 \item in block name must have non-empty label
3 Empty section tag name
-1 \name should only contain printable ASCII characters
-1 Non-ASCII contents without declared encoding
-1 Non-ASCII contents in second part of \enc
-1 Escaped LaTeX specials: ...
-1-3 Lost braces ...
```

- 3 Tag \ldots is invalid in a code block
- 5 \title should not end in a period

and variations with \method replaced by \S3method or \S4method, \dontrun replaced by \donttest, \dontdiff or \dontshow, and \title replaced by \section or \subsection name. “Lost braces” are uprated to warning level -1 when they match common markup mistakes, e.g., ‘code{text}’ rendered as ‘codetext’ due to the missing backslash escape for the macro name.

Note that both prepare_Rd and checkRd have tests for an empty section: that in checkRd is stricter (essentially that nothing is output).

Value

This may fail through an R error, but otherwise warnings are collected as returned as an object of class “checkRd”, a character vector of messages. This class has a print method which only prints unique messages, and has argument minlevel that can be used to select only more serious messages. (This is set to -1 in R CMD check.)

Possible fatal errors are those from !unknownOK or !listOK, from invalid \if or \ifelse conditions, from running the parser (e.g., a non-existent file, unclosed quoted string, non-ASCII input without a specified encoding, an invalid value for an \Sexpr option), or from prepare_Rd (multiple \Rdversion declarations, invalid \encoding or \docType or \name sections, and missing or duplicate \name or \title sections), including errors from parsing/running code from \Sexpr macros (if covered by stages).

[parse_Rd](#), [Rd2HTML](#).

Examples

```
## parsed Rd from the installed version of _this_ help file
rd <- Rd_db("tools")[["checkRd.Rd"]]
rd
stopifnot(length(checkRd(rd)) == 0) # there should be no issues

## make up \tabular issues
bad <- r"(\name{bad}\title{bad}\description{\tabular{p}{1 \tab 2}})"
(res <- checkRd(parse_Rd(textConnection(bad))))
stopifnot(length(res) > 0)
```

checkRdaFiles

*Report on Details of Saved Images or Re-saves them***Description**

This reports for each of the files produced by `save` the size, if it was saved in ASCII or XDR binary format, and if it was compressed (and if so in what format).

Usually such files have extension `‘.rda’` or `‘.RData’`, hence the name of the function.

Usage

```
checkRdaFiles(paths)
resaveRdaFiles(paths, compress = c("auto", "gzip", "bzip2", "xz"),
               compression_level, version = NULL)
```

Arguments

| | |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>paths</code> | A character vector of paths to save files. If this specifies a single directory, it is taken to refer to all <code>‘.rda’</code> and <code>‘.RData’</code> files in that directory. |
| <code>compress, compression_level</code> | Type and level of compression: see save . Values of <code>compress</code> can be abbreviated. |
| <code>version</code> | The format to be used when re-saving: see save . |

Details

`compress = "auto"` asks `R` to choose the compression and ignores `compression_level`. It will try `"gzip"`, `"bzip2"` and if the `"gzip"` compressed size is over 10Kb, `"xz"` and choose the smallest compressed file (but with a 10% bias towards `"gzip"`). This can be slow.

For back-compatibility, `version = NULL` is interpreted to mean version 2: however version-3 files will only be saved as version 3.

Value

For `checkRdaFiles`, a data frame with rows names `paths` and columns

| | |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>size</code> | numeric: file size in bytes, NA if the file does not exist. |
| <code>ASCII</code> | logical: true for <code>save(ASCII = TRUE)</code> , NA if the format is not that of an <code>R</code> save file. |
| <code>compress</code> | character: type of compression. One of <code>"gzip"</code> , <code>"bzip2"</code> , <code>"xz"</code> , <code>"none"</code> or <code>"unknown"</code> (which means that if this is an <code>R</code> save file it is from a later version of <code>R</code>). |
| <code>version</code> | integer: positive with the version(s) of the save() , see there on which versions have been default in which versions of <code>R</code> , and NA for non-Rda files. |

Examples

```
## Not run:
## from a package top-level source directory
paths <- sort(Sys.glob(c("data/*.rda", "data/*.RData")))
(res <- checkRdaFiles(paths))
## pick out some that may need attention
bad <- is.na(res$ASCII) | res$ASCII | (res$size > 1e4 & res$compress == "none")
res[bad, ]

## End(Not run)
```

checkTnF

Check R Packages or Code for T/F

Description

Checks the specified R package or code file for occurrences of T or F, and gathers the expression containing these. This is useful as in R T and F are just variables which are set to the logicals TRUE and FALSE by default, but are not reserved words and hence can be overwritten by the user. Hence, one should always use TRUE and FALSE for the logicals.

Usage

```
checkTnF(package, dir, file, lib.loc = NULL)
```

Arguments

| | |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| package | a character string naming an installed package. If given, the installed R code and the examples in the documentation files of the package are checked. R code installed as an image file cannot be checked. |
| dir | a character string specifying the path to a package's root source directory. This must contain the subdirectory 'R' (for R code), and should also contain 'man' (for documentation). Only used if package is not given. If used, the R code files and the examples in the documentation files are checked. |
| file | the name of a file containing R code to be checked. Used if neither package nor dir are given. |
| lib.loc | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package. |

Value

An object of class "checkTnF" which is a list containing, for each file where occurrences of T or F were found, a list with the expressions containing these occurrences. The names of the list are the corresponding file names.

There is a print method for nicely displaying the information contained in such objects.

checkVignettes

*Check Package Vignettes***Description**

Check all vignettes of a package by running [Sweave](#) (or other custom weave function) and/or [Stangle](#) (or other custom tangle function) on them. All R source code files found after the tangle step are [source](#)d to check whether all code can be executed without errors.

Usage

```
checkVignettes(package, dir, lib.loc = NULL,
               tangle = TRUE, weave = TRUE, latex = FALSE,
               workdir = c("tmp", "src", "cur"),
               keepfiles = FALSE)
```

Arguments

| | |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| package | a character string naming an installed package. If given, vignette source files are looked for in subdirectory ‘doc’. |
| dir | a character string specifying the path to a package’s root source directory. If given, vignette source files are looked for in subdirectory ‘vignettes’. |
| lib.loc | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package. |
| tangle | Perform a tangle and source the extracted code? |
| weave | Perform a weave? |
| latex | logical: if weave and latex are TRUE and there is no ‘Makefile’ in the vignettes directory, run the intermediate ‘.tex’ outputs from weaving through texi2pdf . |
| workdir | Directory used as working directory while checking the vignettes. If “tmp” then a temporary directory is created, this is the default. If “src” then the directory containing the vignettes itself is used, if “cur” then the current working directory of R is used. |
| keepfiles | Delete files in the temporary directory? This option is ignored when workdir != “tmp”. |

Details

This function first uses [pkgVignettes](#) to find the package vignettes, and in particular their vignette engines (see [vignetteEngine](#)).

If tangle is true, it then runs [Stangle](#) (or other custom tangle function provided by the engine) to produce (one or more) R code files from each vignette, then [sources](#) each code file in turn.

If weave is true, the vignettes are run through [Sweave](#) (or other custom weave function provided by the engine). If latex is also true and there is no ‘Makefile’ in the vignettes directory, [texi2pdf](#) is run on the intermediate ‘.tex’ files from weaving for those vignettes which did not give errors in the previous steps.

Value

An object of class "checkVignettes", which is a list with the error messages found during the tangle, source, weave and latex steps. There is a print method for displaying the information contained in such objects.

check_packages_in_dir *Check Source Packages and Their Reverse Dependencies*

Description

Check source packages in a given directory, optionally with their reverse dependencies.

Usage

```
check_packages_in_dir(dir,
                      pfiles = Sys.glob("*.tar.gz"),
                      check_args = character(),
                      check_args_db = list(),
                      reverse = NULL,
                      check_env = character(),
                      xvfb = FALSE,
                      Ncpus = getOption("Ncpus", 1L),
                      clean = TRUE,
                      install_args = list(),
                      parallel_args = list(),
                      ...)

summarize_check_packages_in_dir_results(dir, all = TRUE,
                                       full = FALSE, ...)
summarize_check_packages_in_dir_timings(dir, all = FALSE,
                                       full = FALSE)
summarize_check_packages_in_dir_depends(dir, all = FALSE,
                                       which = c("Depends",
                                                "Imports",
                                                "LinkingTo"))

check_packages_in_dir_changes(dir, old,
                             outputs = FALSE, sources = FALSE, ...)
check_packages_in_dir_details(dir, logs = NULL, drop_ok = TRUE, ...)
```

Arguments

| | |
|--------|--------------------------------------------------------------------------------------------------------------------------|
| dir | a character string giving the path to the directory with the source ‘.tar.gz’ files to be checked. |
| pfiles | (optional) character vector of tarball files to be checked. Useful for choosing a subset of the ‘*.tar.gz’ files in dir. |

| | |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| check_args | a character vector with arguments to be passed to R CMD check, or a list of length two of such character vectors to be used for checking packages and reverse dependencies, respectively. |
| check_args_db | a named list of character vectors with arguments to be passed to R CMD check, with names the respective package names. |
| reverse | a list with names partially matching "repos", "which", or "recursive", giving the repositories to use for locating reverse dependencies (a subset of <code>getOption("repos")</code> , the default), the types of reverse dependencies (default: <code>c("Depends", "Imports", "LinkingTo")</code> , with shorthands "most" and "all" as for package_dependencies), and indicating whether to also check reverse dependencies of reverse dependencies and so on (default: FALSE), or NULL (default), in which case no reverse dependencies are checked. |
| check_env | a character vector of name=value strings to set environment variables for checking, or a list of length two of such character vectors to be used for checking packages and reverse dependencies, respectively. |
| xvfb | a logical indicating whether to perform checking inside a virtual framebuffer X server (Unix only), or a character vector of Xvfb options for doing so. |
| Ncpus | the number of parallel processes to use for parallel installation and checking. |
| clean | a logical indicating whether to remove the downloaded reverse dependency sources. |
| install_args | list of arguments to be passed to underlying install.packages call. |
| parallel_args | list of arguments to be passed to underlying calls of parLapply (on Windows) or mclapply (on other OS). |
| ... | passed to readLines , e.g. for reading log files produced in a different encoding; currently not used by <code>check_packages_in_dir</code> . |
| all | a logical indicating whether to also summarize the reverse dependencies checked. |
| full | a logical indicating whether to also give details for checks with non-ok results, or summarize check example timings (if available). |
| which | see package_dependencies . |
| old | a character string giving the path to the directory of a previous <code>check_packages_in_dir</code> run. |
| outputs | a logical indicating whether to analyze changes in the outputs of the checks performed, or only (default) the status of the checks. |
| sources | a logical indicating whether to also investigate the changes in the source files checked (default: FALSE). |
| logs | a character vector with the paths of '00check.log' to analyze. Only used if <code>dir</code> was not given. |
| drop_ok | a logical indicating whether to drop checks with 'ok' status, or a character vector with the 'ok' status tags to drop. The default corresponds to tags 'OK', 'NONE' and 'SKIPPED'. |

Details

check_packages_in_dir allows to conveniently check source package `‘.tar.gz’` files in the given directory `dir`, along with their reverse dependencies as controlled by `reverse`.

The `"which"` component of `reverse` can also be a list, in which case reverse dependencies are obtained for each element of the list and the corresponding element of the `"recursive"` component of `reverse` (which is recycled as needed).

If needed, the source `‘.tar.gz’` files of the reverse dependencies to be checked as well are downloaded into `dir` (and removed at the end if `clean` is true). Next, all packages (additionally) needed for checking are installed to the `‘Library’` subdirectory of `dir`. Then, all `‘.tar.gz’` files are checked using the given arguments and environment variables, with outputs and messages to files in the `‘Outputs’` subdirectory of `dir`. The `‘*.Rcheck’` directories with the check results of the reverse dependencies are renamed by prefixing their base names with `‘rdepends_’`.

Results and timings can conveniently be summarized using `summarize_check_packages_in_dir_results` and `summarize_check_packages_in_dir_timings`, respectively.

Installation and checking is performed in parallel if `Ncpus` is greater than one: this will use `mclapply` on Unix and `parLapply` on Windows.

`check_packages_in_dir` returns an object inheriting from class `"check_packages_in_dir"` which has `print` and `summary` methods.

`check_packages_in_dir_changes` allows to analyze the effect of changing (some of) the sources. With `dir` and `old` the paths to the directories with the new and old sources, respectively, and the corresponding check results, possible changes in the check results can conveniently be analyzed as controlled via options `outputs` and `sources`. The `changes` object returned can be subscripted according to change in severity from the old to the new results by using one of `"=="`, `"!="`, `"<"`, `"<="`, `">"` or `">="` as row index.

`check_packages_in_dir_details` analyzes check log files to obtain check details as a data frame which can be used for further processing, providing check name, status and output for every check performed and not dropped according to status tag (via variables `Check`, `Status` and `Output`, respectively).

Environment variable `_R_CHECK_ELAPSED_TIMEOUT_` can be used to set a limit on the elapsed time of each check run. See the `‘R Internals’` manual for how the value is interpreted and for other environment variables which can be used for finer-grained control on timeouts within a check run.

Note

This functionality is still experimental: interfaces may change in future versions.

Examples

```
## Not run:
## Check packages in dir without reverse dependencies:
check_packages_in_dir(dir)
## Check packages in dir and their reverse dependencies using the
## defaults (all repositories in getOption("repos"), all "strong"
## reverse dependencies, no recursive reverse dependencies):
check_packages_in_dir(dir, reverse = list())
```

```
## Check packages in dir with their reverse dependencies from CRAN,
## using all strong reverse dependencies and reverse suggests:
check_packages_in_dir(dir,
                      reverse = list(repos = getOption("repos")["CRAN"],
                                     which = "most"))
## Check packages in dir with their reverse dependencies from CRAN,
## using '--as-cran' for the former but not the latter:
check_packages_in_dir(dir,
                      check_args = c("--as-cran", ""),
                      reverse = list(repos = getOption("repos")["CRAN"]))

## End(Not run)
```

codoc

Check Code/Documentation Consistency

Description

Find inconsistencies between actual and documented ‘structure’ of R objects in a package. codoc compares names and optionally also corresponding positions and default values of the arguments of functions. codocClasses and codocData compare slot names of S4 classes and variable names of data sets, respectively.

Usage

```
codoc(package, dir, lib.loc = NULL,
      use.values = NULL, verbose = getOption("verbose"))
codocClasses(package, lib.loc = NULL)
codocData(package, lib.loc = NULL)
```

Arguments

| | |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| package | a character string naming an installed package. |
| dir | a character string specifying the path to a package’s root source directory. This must contain the subdirectories ‘man’ with R documentation sources (in Rd format) and ‘R’ with R code. Only used if package is not given. |
| lib.loc | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package. |
| use.values | if FALSE, do not use function default values when comparing code and docs. Otherwise, compare <i>all</i> default values if TRUE, and only the ones documented in the usage otherwise (default). |
| verbose | a logical. If TRUE, additional diagnostics are printed. |

Details

The purpose of `codoc` is to check whether the documented usage of function objects agrees with their formal arguments as defined in the R code. This is not always straightforward, in particular as the usage information for methods to generic functions often employs the name of the generic rather than the method.

The following algorithm is used. If an installed package is used, it is loaded (unless it is the **base** package), after possibly detaching an already loaded version of the package. Otherwise, if the sources are used, the R code files of the package are collected and sourced in a new environment. Then, the usage sections of the Rd files are extracted and parsed ‘as much as possible’ to give the formals documented. For interpreted functions in the code environment, the formals are compared between code and documentation according to the values of the argument `use.values`.

If a package has a namespace both exported and unexported objects are checked, as well as registered S3 methods. (In the unlikely event of differences the order is exported objects in the package, registered S3 methods and finally objects in the namespace and only the first found is checked.)

Currently, the R documentation format has no high-level markup for the basic ‘structure’ of classes and data sets (similar to the usage sections for function synopses). Variable names for data frames in documentation objects obtained by suitably editing ‘templates’ created by [prompt](#) are recognized by `codocData` and used provided that the documentation object is for a single data frame (i.e., only has one alias). `codocClasses` analogously handles slot names for classes in documentation objects obtained by editing shells created by [promptClass](#).

Help files named ‘*pkgname*-defunct.Rd’ for the appropriate *pkgname* are checked more loosely, as they may have undocumented arguments.

Value

`codoc` returns an object of class “`codoc`”. Currently, this is a list which, for each Rd object in the package where an inconsistency was found, contains an element with a list of the mismatches (which in turn are lists with elements `code` and `docs`, giving the corresponding arguments obtained from the function’s code and documented usage).

`codocClasses` and `codocData` return objects of class “`codocClasses`” and “`codocData`”, respectively, with a structure similar to class “`codoc`”.

There are print methods for nicely displaying the information contained in such objects.

Note

The default for `use.values` has been changed from `FALSE` to `NULL`, for R versions 1.9.0 and later.

[undoc](#), [QC](#)

Description

Re-save PDF files (especially vignettes) more compactly. Support function for R CMD build --compact-vignettes.

Usage

```
compactPDF(paths,
            qpdf = Sys.which(Sys.getenv("R_QPDF", "qpdf")),
            gs_cmd = Sys.getenv("R_GSCMD", ""),
            gs_quality = Sys.getenv("GS_QUALITY", "none"),
            gs_extras = character(),
            verbose = FALSE)
```

```
## S3 method for class 'compactPDF'
format(x, ratio = 0.9, diff = 1e4, ...)
```

Arguments

| | |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| paths | A character vector of paths to PDF files, or a length-one character vector naming a directory, when all '.pdf' files in that directory will be used. |
| qpdf | Character string giving the path to the qpdf command. If empty, qpdf will not be used. |
| gs_cmd | Character string giving the path to the GhostScript executable, if that is to be used. On Windows this is the path to 'gswin32c.exe' or 'gswin64c.exe'. If "" (the default), the function will try to find a platform-specific path to GhostScript where required. |
| gs_quality | A character string indicating the quality required: the options are "none" (so GhostScript is not used), "printer" (300dpi), "ebook" (150dpi) and "screen" (72dpi). Can be abbreviated. |
| gs_extras | An optional character vector of further options to be passed to GhostScript. |
| verbose | logical or non-negative integer indicating if and how much of the compression utilities' output should be shown. |
| x | An object of class "compactPDF". |
| ratio, diff | Limits for reporting: files are only reported whose sizes are reduced both by a factor of ratio and by diff bytes. |
| ... | Further arguments to be passed to or from other methods. |

Details

This by default makes use of qpdf, available from <https://qpdf.sourceforge.io/> (including as a Windows binary) and included with the CRAN macOS distribution of R. If `gs_cmd` is non-empty and `gs_quality != "none"`, GhostScript will be used first, then qpdf if it is available. If `gs_quality != "none"` and `gs_cmd` is "", an attempt will be made to find a GhostScript executable.

qpdf and/or `gs_cmd` are run on all PDF files found, and those which are reduced in size by at least 10% and 10Kb are replaced.

The strategy of our use of qpdf is to (losslessly) compress both PDF streams and objects. GhostScript compresses streams and more (including downsampling and compressing embedded images) and consequently is much slower and may lose quality (but can also produce much smaller PDF files). However, quality "ebook" is perfectly adequate for screen viewing and printing on laser printers.

Where PDF files are changed they will become PDF version 1.5 files: these have been supported by Acrobat Reader since version 6 in 2003, so this is very unlikely to cause difficulties.

Stream compression is what most often has large gains. Most PDF documents are generated with object compression, but this does not seem to be the default for MiKTeX's pdf_latex. For some PDF files (and especially package vignettes), using GhostScript can dramatically reduce the space taken by embedded images (often screenshots).

Where both GhostScript and qpdf are selected (when `gs_quality != "none"` and both executables are found), they are run in that order and the size reductions apply to the total compression achieved.

Value

An object of class `c("compactPDF", "data.frame")`. This has two columns, the old and new sizes in bytes for the files that were changed.

There are `format` and `print` methods: the latter passes ... to the `format` method, so will accept `ratio` and `diff` arguments.

Note

The external tools used may change in future releases.

Frequently, updates to GhostScript have produced better compression (up to several times better), so if possible use the latest version available.

See Also

[resaveRdaFiles](#).

For other tools to compact PDF files, see the 'Writing R Extensions' manual.

Description

Tools for obtaining information about current packages in the CRAN package repository, and their check status.

Usage

```
CRAN_package_db()

CRAN_check_results(flavors = NULL)
CRAN_check_details(flavors = NULL)
CRAN_check_issues()
summarize_CRAN_check_status(packages,
                             results = NULL,
                             details = NULL,
                             issues = NULL)
```

Arguments

| | |
|-----------------------|-----------------------------------------------------------------------------------------------------------|
| <code>packages</code> | a character vector of package names. |
| <code>flavors</code> | a character vector of CRAN check flavor names, or NULL (default), corresponding to all available flavors. |
| <code>results</code> | the return value of <code>CRAN_check_results()</code> (default), or a subset of this. |
| <code>details</code> | the return value of <code>CRAN_check_details()</code> (default), or a subset of this. |
| <code>issues</code> | the return value of <code>CRAN_check_issues()</code> (default), or a subset of this. |

Details

`CRAN_package_db()` returns a data frame with character columns containing most 'DESCRIPTION' metadata for the current packages in the CRAN package repository, including in particular the Description and Maintainer information not provided by `utils::available.packages()`.

`CRAN_check_results()` returns a data frame with the basic CRAN package check results including timings, with columns `Package`, `Flavor` and `Status` giving the package name, check flavor, and overall check status, respectively.

`CRAN_check_details()` returns a data frame inheriting from class "check_details" (which has useful `print` and `format` methods) with details on the check results, providing check name, status and output for every non-OK check (*via* columns `Check`, `Status` and `Output`, respectively). Packages with all-OK checks are indicated via a `* Check` wildcard name and OK Status.

`CRAN_check_issues()` returns a character frame with additional check issues (including the memory-access check results made available from <https://www.stats.ox.ac.uk/pub/bdr/memtests/>) as a character frame with variables `Package`, `Version`, `kind` (an identifier for the issue) and `href` (a URL with information on the issue).

Value

See ‘Details’. Note that the results are collated on CRAN: currently this is done in a locale which sorts aAbB....

Which CRAN?

The main functions access a CRAN mirror specified by the environment variable `R_CRAN_WEB`, defaulting to one specified in the “repos” option. Otherwise the entry in the ‘repositories’ file (see `setRepositories`) is used: if that specifies ‘@CRAN@’ (the default) or does not contain an entry for CRAN then <https://CRAN.R-project.org> is used.

The mirror to be used is reported by `utils::findCRANmirror("web")`.

Note that these functions access parts of CRAN under ‘web/contrib’ and ‘web/packages’ so if you have specified a mirror of just ‘src/contrib’ for installing packages you will need to set `R_CRAN_WEB` to point to a full mirror.

Internal functions `CRAN_aliases_db`, `CRAN_archive_db`, `CRAN_current_db` and `CRAN_rdxrefs_db` (used by R CMD check) use `R_CRAN_SRC` rather than `R_CRAN_WEB`.

Examples

```
## This can be rather slow with a non-local CRAN mirror
## and might fail (slowly) without Internet access in that case.

set.seed(11) # but the packages chosen will change as soon as CRAN does.
pdb <- CRAN_package_db()
dim(pdb)
## DESCRIPTION fields included:
colnames(pdb)
## Summarize publication dates:
summary(as.Date(pdb$Published))
## Summarize numbers of packages according to maintainer:
summary(lengths(split(pdb$Package, pdb$Maintainer)))
## Packages with 'LASSO' in their Description:
pdb$Package[grepl("LASSO", pdb$Description)]

results <- CRAN_check_results()
## Available variables:
names(results)
## Tabulate overall check status according to flavor:
with(results, table(Flavor, Status))

details <- CRAN_check_details()
## Available variables:
names(details)
## Tabulate checks according to their status:
tab <- with(details, table(Check, Status))
## Inspect some installation problems:
bad <- subset(details,
              ((Check == "whether package can be installed") &
               (Status != "OK")))
## Show a random sample of up to 6
```

```

head(bad[sample(seq_len(NROW(bad)), NROW(bad)), ])

issues <- CRAN_check_issues()
head(issues)
## Show counts of issues according to kind:
table(issues[, "kind"])

## Summarize CRAN check status for 10 randomly-selected packages
## (reusing the information already read in):
pos <- sample(seq_len(NROW(pdb)), 10L)
summarize_CRAN_check_status(pdb[pos, "Package"],
                             results, details, issues)

```

delimMatch

*Delimited Pattern Matching***Description**

Match delimited substrings in a character vector, with proper nesting.

Usage

```
delimMatch(x, delim = c("{", "}"), syntax = "Rd")
```

Arguments

| | |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code> | a character vector. |
| <code>delim</code> | a character vector of length 2 giving the start and end delimiters. Future versions might allow for arbitrary regular expressions. |
| <code>syntax</code> | currently, always the string "Rd" indicating Rd syntax (i.e., '%' starts a comment extending till the end of the line, and '\' escapes). Future versions might know about other syntax, perhaps via 'syntax tables' allowing to flexibly specify comment, escape, and quote characters. |

Value

An integer vector of the same length as `x` giving the starting position (in characters) of the first match, or `-1` if there is none, with attribute `"match.length"` giving the length (in characters) of the matched text (or `-1` for no match).

See Also

[regexr](#) for 'simple' pattern matching.

Examples

```

x <- c("\\value{foo}", "function(bar)")
delimMatch(x)
delimMatch(x, c("(", ")"))

```

dependsOnPkgs

Find Reverse Dependencies

Description

Find ‘reverse’ dependencies of packages, that is those packages which depend on this one, and (optionally) so on recursively.

Usage

```
dependsOnPkgs(pkgs,
              dependencies = "strong",
              recursive = TRUE, lib.loc = NULL,
              installed =
                utils::installed.packages(lib.loc, fields = "Enhances"))
```

Arguments

| | |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pkgs | a character vector of package names. |
| dependencies | a character vector listing the types of dependencies, a subset of c("Depends", "Imports", "LinkingTo", "Suggests", "Enhances"). Character string "all" is shorthand for that vector, character string "most" for the same vector without "Enhances", character string "strong" (default) for the first three elements of that vector. |
| recursive | logical: should reverse dependencies of reverse dependencies (and so on) be included? |
| lib.loc | a character vector of R library trees, or NULL for all known trees (see .libPaths). |
| installed | a result of calling installed.packages . |

Value

A character vector of package names, which does not include any from pkgs.

See Also

[package_dependencies\(\)](#) to get the regular (“forward”) dependencies of a package.

Examples

```
## there are few dependencies in a vanilla R installation:
## lattice may not be installed
dependsOnPkgs("lattice")
```

encoded_text_to_latex *Translate non-ASCII Text to LaTeX Escapes*

Description

Translate non-ASCII characters in text to LaTeX escape sequences.

Usage

```
encoded_text_to_latex(x,  
                      encoding = c("latin1", "latin2", "latin9",  
                                   "UTF-8", "utf8"))
```

Arguments

| | |
|----------|-----------------------------------------------------------------------------------------------------------------------------|
| x | a character vector. |
| encoding | the encoding to be assumed. "latin9" is officially ISO-8859-15 or Latin-9, but known as latin9 to LaTeX's inputenc package. |

Details

Non-ASCII characters in x are replaced by an appropriate LaTeX escape sequence, or '?' if there is no appropriate sequence.

Even if there is an appropriate sequence, it may not be supported by the font in use. Hyphen is mapped to '\-'.

Value

A character vector of the same length as x.

See Also

writeLines(paste0(xx, "\\\"), con)
writeLines(trailer, con)
close(con)
## and some UTF_8 chars
x <- intToUtf8(as.integer(
  c(160:383,0x0192,0x02C6,0x02C7,0x02CA,0x02D8,
    0x02D9, 0x02DD, 0x200C, 0x2018, 0x2019, 0x201C,
    0x201D, 0x2020, 0x2022, 0x2026, 0x20AC)),
  multiple = TRUE)
x <- matrix(x, ncol = 16, byrow = TRUE)
xx <- x
xx[] <- encoded_text_to_latex(x, "UTF-8")
xx <- apply(xx, 1, paste, collapse = "&")
con <- file("test-utf8.tex", "w")
writeLines(header, con)
writeLines(paste(xx, "\\\"), sep = ""), con)
writeLines(trailer, con)
close(con)

## End(Not run)

```

fileutils

File Utilities

Description

Utilities for listing files, and manipulating file paths.

Usage

```

file_ext(x)
file_path_as_absolute(x)
file_path_sans_ext(x, compression = FALSE)

list_files_with_exts(dir, exts, all.files = FALSE,
  full.names = TRUE)
list_files_with_type(dir, type, all.files = FALSE,
  full.names = TRUE, OS_subdirs = .OSType())

```

Arguments

| | |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code> | character vector giving file paths. |
| <code>compression</code> | logical: should compression extension <code>‘.gz’</code> , <code>‘.bz2’</code> or <code>‘.xz’</code> be removed first? |
| <code>dir</code> | a character string with the path name to a directory. |
| <code>exts</code> | a character vector of possible file extensions (excluding the leading dot). |
| <code>all.files</code> | a logical. If FALSE (default), only visible files are considered; if TRUE, all files are used. |
| <code>full.names</code> | a logical indicating whether the full paths of the files found are returned (default), or just the file names. |
| <code>type</code> | a character string giving the ‘type’ of the files to be listed, as characterized by their extensions. Currently, possible values are <code>"code"</code> (R code), <code>"data"</code> (data sets), <code>"demo"</code> (demos), <code>"docs"</code> (R documentation), and <code>"vignette"</code> (vignettes). |
| <code>OS_subdirs</code> | a character vector with the names of OS-specific subdirectories to possibly include in the listing of R code and documentation files. By default, the value of the environment variable <code>R_OSTYPE</code> , or if this is empty, the value of <code>.Platform\$OS.type</code> , is used. |

Details

`file_ext` returns the file (name) extensions (excluding the leading dot). (Only purely alphanumeric extensions are recognized.)

`file_path_as_absolute` turns a possibly relative file path absolute, performing tilde expansion if necessary. This is a wrapper for `normalizePath`. Currently, `x` must be a single existing path.

`file_path_sans_ext` returns the file paths without extensions (and the leading dot). (Only purely alphanumeric extensions are recognized.)

`list_files_with_exts` returns the paths or names of the files in directory `dir` with extension matching one of the elements of `exts`. Note that by default, full paths are returned, and that only visible files are used.

`list_files_with_type` returns the paths of the files in `dir` of the given ‘type’, as determined by the extensions recognized by R. When listing R code and documentation files, files in OS-specific subdirectories are included if present according to the value of `OS_subdirs`. Note that by default, full paths are returned, and that only visible files are used.

See Also

[file.path](#), [file.info](#), [list.files](#)

Examples

```
dir <- file.path(R.home(), "library", "stats")
list_files_with_exts(file.path(dir, "demo"), "R")
list_files_with_type(file.path(dir, "demo"), "demo") # the same
file_path_sans_ext(list.files(file.path(R.home("modules"))))
```

`find_gs_cmd`*Find a GhostScript Executable*

Description

Find a GhostScript executable in a cross-platform way.

Usage

```
find_gs_cmd(gs_cmd = "")
```

Arguments

`gs_cmd` The name, full or partial path of a GhostScript executable.

Details

The details differ by platform.

On a Unix-alike, the GhostScript executable is usually called `gs`. The name (and possibly path) of the command is taken first from argument `gs_cmd` then from the environment variable `R_GSCMD` and default `gs`. This is then looked for on the system path and the value returned if a match is found.

On Windows, the name of the command is taken from argument `gs_cmd` then from the environment variables `R_GSCMD` and `GSC`. If neither of those produces a suitable command name, `gswin64c` and `gswin32c` are tried in turn. In all cases the command is looked for on the system `PATH`.

Note that on Windows (and some other OSes) there are separate GhostScript executables to display Postscript/PDF files and to manipulate them: this function looks for the latter.

Value

A character string giving the full path to a GhostScript executable if one was found, otherwise an empty string.

Examples

```
## Not run:
## Suppose a Solaris system has GhostScript 9.00 on the path and
## 9.07 in /opt/csw/bin. Then one might set
Sys.setenv(R_GSCMD = "/opt/csw/bin/gs")

## End(Not run)
```

`getVignetteInfo`*Get Information on Installed Vignettes*

Description

This function gets information on installed vignettes.

Usage

```
getVignetteInfo(package = NULL, lib.loc = NULL, all = TRUE)
```

Arguments

| | |
|----------------------|----------------------------------------------------------------------|
| <code>package</code> | Which package to look in, or NULL for all packages. |
| <code>lib.loc</code> | Which library to look in. |
| <code>all</code> | Whether to search all installed packages, or just attached packages. |

Value

A matrix with columns

| | |
|---------|-------------------------------------------------|
| Package | the name of the package |
| Dir | the directory where the package is installed |
| Topic | the name of the vignette |
| File | the base filename of the source of the vignette |
| Title | the title of the vignette |
| R | the tangled R source from the vignette |
| PDF | the PDF or HTML file for display |

Note

The last column of the result is named PDF for historical reasons, but it may contain a filename of a PDF or HTML document.

See Also

[pkgVignettes](#) is a similar function that can work on an uninstalled package.

Examples

```
getVignetteInfo("grid")
```

Description

This function generates the standard HTML header used on R help pages.

Usage

```
HTMLheader(title = "R", logo = TRUE, up = NULL,
            top = file.path(Rhome, "doc/html/index.html"),
            Rhome = "",
            css = file.path(Rhome, "doc/html/R.css"),
            headerTitle = paste("R:", title),
            outputEncoding = "UTF-8")
```

Arguments

| | |
|----------------|---------------------------------------------------------------------------------------------------|
| title | The title to display and use in the HTML headers. Should have had any HTML escaping already done. |
| logo | Whether to display the R logo after the title. |
| up | Which page (if any) to link to on the “up” button. |
| top | Which page (if any) to link to on the “top” button. |
| Rhome | A relative path to the R home directory. See the ‘Details’. |
| css | The relative URL for the Cascading Style Sheet. |
| headerTitle | The title used in the headers. |
| outputEncoding | The declared encoding for the whole page. |

Details

The up and top links should be relative to the current page. The Rhome path default works with dynamic help; for static help, a relative path (e.g., ‘. / . .’) to it should be used.

Value

A character vector containing the lines of an HTML header which can be used to start a page in the R help system.

Examples

```
cat(HTMLheader("This is a sample header"), sep="\n")
```

HTMLlinks*Collect HTML Links from Package Documentation*

Description

Compute relative file paths for URLs to other package's installed HTML documentation.

Usage

```
findHTMLlinks(pkgDir = "", lib.loc = NULL, level = 0:2)
```

Arguments

| | |
|----------------------|-----------------------------------------------------------------------------------------------------------------------|
| <code>pkgDir</code> | the top-level directory of an installed package. The default indicates no package. |
| <code>lib.loc</code> | character vector describing the location of R library trees to scan: the default indicates <code>.libPaths()</code> . |
| <code>level</code> | Which level(s) to include. |

Details

`findHTMLlinks` tries to resolve links from one help page to another. It uses in decreasing priority

- The package in `pkgDir`: this is used when converting HTML help for that package (level 0).
- The base and recommended packages (level 1).
- Other packages found in the library trees specified by `lib.loc` in the order of the trees and alphabetically within a library tree (level 2).

Value

A named character vector of file paths, relative to the 'html' directory of an installed package. So these are of the form `"../.. /somepkg/html/sometopic.html"`.

Author(s)

Duncan Murdoch, Brian Ripley

loadRdMacros*Load User-defined Rd Help System Macros*

Description

Loads macros from an ‘.Rd’ file, or from several ‘.Rd’ files contained in a package.

Usage

```
loadRdMacros(file, macros = TRUE)
loadPkgRdMacros(pkgdir, macros = NULL)
```

Arguments

| | |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| file | A file in Rd format containing macro definitions. |
| macros | optionally, a previous set of macro definitions, in the format expected by the parse_Rd macros argument. loadPkgRdMacros loads the system Rd macros by default. |
| pkgdir | The base directory of a source package or an installed package. |

Details

The Rd files parsed by these functions should contain only macro definitions; a warning will be issued if anything else other than comments or white space is found.

The macros argument may be a filename of a base set of macros, or the result of a previous call to loadRdMacros or loadPkgRdMacros in the same session. These results should be assumed to be valid only within the current session.

The loadPkgRdMacros function first looks for an “RdMacros” entry in the package ‘DESCRIPTION’ file. If present, it should contain a comma-separated list of other package names; their macros will be loaded before those of the current package. It will then look in the current package for ‘.Rd’ files in the ‘man/macros’ or ‘help/macros’ subdirectories, and load those.

Value

These functions each return an environment containing objects with the names of the newly defined macros from the last file processed. The parent environment will be macros from the previous file, and so on. The first file processed will have [emptyenv\(\)](#) as its parent.

Author(s)

Duncan Murdoch

References

See the ‘Writing R Extensions’ manual for the syntax of Rd files, or <https://developer.r-project.org/parseRd.pdf> for a technical discussion.

See Also[parse_Rd](#)**Examples**

```
f <- tempfile()
writeLines(r"(
\newcommand{\Rlogo}{
  \if{html}{\figure{Rlogo.svg}{options: width=100 alt="R logo"}}
  \if{latex}{\figure{Rlogo.pdf}{options: width=0.5in}}
}
)", f)
m <- loadRdMacros(f)
ls(m)
ls(parent.env(m))
ls(parent.env(parent.env(m)))
parse_Rd(textConnection(r"(\Rlogo)"), fragment = TRUE, macros = m)
```

makevars

*User and Site Compilation Variables***Description**

Determine the location of the user and site specific ‘Makevars’ files for customizing package compilation.

Usage

```
makevars_user()
makevars_site()
```

Details

Package maintainers can use these functions to employ user and site specific compilation settings also for compilations not using R’s mechanisms (in particular, custom compilations in subdirectories of ‘src’), e.g., by adding configure code calling R with `cat(tools::makevars_user())` or `cat(tools::makevars_site())`, and if non-empty passing this with ‘-f’ to custom Make invocations.

Value

A character string with the path to the user or site specific ‘Makevars’ file, or an empty character vector if there is no such file.

See Also

Section ‘Customizing package compilation’ in the ‘R Installation and Administration’ manual.

Examples

```
makevars_user()
makevars_site()
```

| | |
|-----------------------|----------------------------------------------------------|
| make_translations_pkg | <i>Package the Current Translations in the R Sources</i> |
|-----------------------|----------------------------------------------------------|

Description

A utility for R Core members to prepare a package of updated translations.

Usage

```
make_translations_pkg(srcdir, outDir = ".", append = "-1")
```

Arguments

| | |
|--------|-------------------------------------------------------------------------------------------|
| srcdir | The R source directory. |
| outDir | The directory into which to place the prepared package. |
| append | The suffix for the package version number, e.g. ‘3.0.0-1’ will be the default in R 3.0.0. |

Details

This extracts the translations in a current R source distribution and packages them as a source package called **translations** which can be distributed on CRAN and installed by [update.packages](#). This allows e.g. the translations shipped in R 3.x.y to be updated to those currently in ‘R-patched’, even by a user without administrative privileges.

The package has a ‘Depends’ field which restricts it to versions ‘3.x.*’ for a single x.

| | |
|------------------|----------------------------------------------------|
| matchConcordance | <i>Concordance between source and target lines</i> |
|------------------|----------------------------------------------------|

Description

The Rd parser records locations in ‘.Rd’ files from which components of the file are read. Output generators [Rd2HTML](#) and [Rd2latex](#) can output information about these locations as “concordances” between source and output lines.

matchConcordance converts from output locations to source locations. The “Rconcordance” method of as.character produces strings to embed in output files, and the default method of as.Rconcordance converts these back to objects that can be interpreted by matchConcordance.

Usage

```

matchConcordance(linenum, concordance)
## S3 method for class 'Rconcordance'
as.character(x, targetfile = "", ...)
as.Rconcordance(x, ...)
followConcordance(concordance, prevConcordance)

```

Arguments

| | |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| linenum | One or more line numbers being queried. |
| concordance | The concordance data for the file containing the lines: an object of class "Rconcordance". |
| prevConcordance | A concordance object retrieved from the current file. |
| targetfile | The output filename. |
| x | The object to convert: for as.character, an "Rconcordance" object; for as.concordance, a character vector which contains as.character output, typically in comments. |
| ... | Further arguments passed to other methods. |

Details

The correspondence between target lines and source lines in Rd file conversion is not one to one. Often a single source line can lead to the generation of multiple output lines, and sometimes more than one source line triggers output on the same output line.

matchConcordance converts from target lines to source lines. This can be used to help in understanding how particular output lines depend on the source, e.g. when an error is found in the output file. When more than one line contributes to the output, the last one will be returned.

The "Rconcordance" method of as.character converts a concordance object to strings suitable for embedding (e.g. in comments) in an output file.

The default method of as.Rconcordance searches for strings matching the pattern of as.character.Rconcordance output, then converts those lines back to a single concordance.

followConcordance is used when a file is transformed more than once. The first transformation records a concordance in the file which is read as prevConcordance. followConcordance chains this with the current concordance, relating the final result to the original source.

There are 3 kinds of objects used to hold concordances.

Objects of class "activeConcordance" are internal to **tools**; they are used by Rd2HTML and Rd2latex while building the output file and saving links to the source file.

Objects of class "Rconcordance" are visible to users. They are list objects with the following three fields:

offset The number of lines of output before the first one corresponding to this concordance.

srcLine For each line of output after the offset, the corresponding input file line number. There may be more lines of output than the length of srcLine, in which case nothing can be inferred about the source of those lines.

`srcFile` A vector of filenames of length 1 or the same length as `srcLine` giving the source file(s) for each output line.

Concordance strings are produced by the "Rconcordance" method of `as.character`; they are simply character vectors encoding the concordance data. The default method of the `as.concordance` generic function converts them to "Rconcordance" objects.

Value

`matchConcordance` returns a character array with one row per input `linenum` entry and two columns, "srcFile" and "srcLine".

For the "Rconcordance" method of `as.character`, a character vector used (e.g. in [Sweave](#)) to embed the concordance in a file.

For `as.concordance`, an "Rconcordance" object, or NULL if no concordance strings are found.

[Rd2HTML](#), [Rd2latex](#)

md5sum

Compute MD5 Checksums

Description

Compute the 32-byte MD5 hashes of one or more files.

Usage

```
md5sum(files)
```

Arguments

`files` character. The paths of file(s) whose contents are to be hashed.

Details

A MD5 'hash' or 'checksum' or 'message digest' is a 128-bit summary of the file contents represented by 32 hexadecimal digits. Files with different MD5 sums are different: only very exceptionally (and usually with the intent to deceive) are those with the same sums different.

On Windows all files are read in binary mode (as the `md5sum` utilities there do); on other OSes the files are read in the default mode (almost always text mode where there is more than one).

MD5 sums are used as a check that R packages have been unpacked correctly and not subsequently accidentally modified.

Value

A character vector of the same length as `files`, with names equal to `files` (possibly expanded). The elements will be `NA` for non-existent or unreadable files, otherwise a 32-character string of hexadecimal digits.

Source

The underlying C code was written by Ulrich Drepper and extracted from a 2001 release of `glibc`.

See Also

[checkMD5sums](#)

Examples

```
as.vector(md5sum(dir(R.home(), pattern = "^COPY", full.names = TRUE)))
```

package_dependencies *Computations on the Dependency Hierarchy of Packages*

Description

Find (recursively) dependencies or reverse dependencies of packages.

Usage

```
package_dependencies(packages = NULL, db = NULL, which = "strong",
  recursive = FALSE, reverse = FALSE,
  verbose = getOption("verbose"))
```

Arguments

| | |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>packages</code> | a character vector of package names. |
| <code>db</code> | character matrix as from available.packages() (with the default <code>NULL</code> the results of this call) or data frame variants thereof. Alternatively, a package database like the one available from https://cran.r-project.org/web/packages/packages.rds . |
| <code>which</code> | a character vector listing the types of dependencies, a subset of <code>c("Depends", "Imports", "LinkingTo", "Suggests", "Enhances")</code> . Character string "all" is shorthand for that vector, character string "most" for the same vector without "Enhances", character string "strong" (default) for the first three elements of that vector. |
| <code>recursive</code> | a logical indicating whether (reverse) dependencies of (reverse) dependencies (and so on) should be included, or a character vector like <code>which</code> indicating the type of (reverse) dependencies to be added recursively. |
| <code>reverse</code> | logical: if <code>FALSE</code> (default), regular dependencies are calculated, otherwise reverse dependencies. |
| <code>verbose</code> | logical indicating if output should monitor the package search cycles. |

Value

Named list with one element for each package in argument `packages`, each consists of a character vector naming the (recursive) (reverse) dependencies of that package.

For given packages which are not found in the db, NULL entries are returned, as opposed to `character(0)` entries which indicate no dependencies.

See Also

[dependsOnPkgs](#).

Examples

```
myPkgs <- c("MASS", "Matrix", "KernSmooth", "class", "cluster", "codetools")
pdb <- available.packages(repos = findCRANmirror("web"))
system.time(
  dep1 <- package_dependencies(myPkgs, db = pdb) # all arguments at default
) # very fast
utils::str(dep1, vec.len=10)

system.time( ## reverse dependencies, recursively --- takes much longer:
  deps <- package_dependencies(myPkgs, db = pdb, which = "most",
                             recursive = TRUE, reverse = TRUE)
) # seen ~ 10 seconds

lengths(deps) # 2020-05-03: all are 16053, but codetools with 16057

## install.packages(dependencies = TRUE) installs 'most' dependencies
## and the strong recursive dependencies of these: these dependencies
## can be obtained using 'which = "most"' and 'recursive = "strong"'.
## To illustrate on the first packages with non-missing Suggests:
packages <- pdb[head(which(!is.na(pdb[, "Suggests"]))), "Package"]
package_dependencies(packages, db = pdb,
                    which = "most", recursive = "strong")
```

package_native_routine_registration_skeleton

Write Skeleton for Adding Native Routine Registration to a Package

Description

Write a skeleton for adding native routine registration to a package.

Usage

```
package_native_routine_registration_skeleton(dir, con = stdout(),
  align = TRUE, character_only = TRUE, include_declarations = TRUE)
```

Arguments

| | |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dir</code> | Top-level directory of a package. |
| <code>con</code> | Connection on which to write the skeleton: can be specified as a file path. |
| <code>align</code> | Logical: should the registration tables be lined up in three columns each? |
| <code>character_only</code> | Logical: should only <code>.NAME</code> arguments specified by character strings (and not as names of R objects nor expressions) be extracted? |
| <code>include_declarations</code> | Logical: should the output include declarations (also known as ‘prototypes’) for the registered routines? |

Details

Registration is described in section ‘Registering native routines’ of ‘Writing R Extensions’. This function produces a skeleton of the C code which needs to be added to enable registration, conventionally as file ‘src/init.c’ or appended to the sole C file of the package.

This function examines the code in the ‘R’ directory of the package for calls to `.C`, `.Fortran`, `.Call` and `.External` and creates registration information for those it can make sense of. If the number of arguments used cannot be determined it will be recorded as `-1`: such values should be corrected.

Optionally the skeleton will include declarations for the registered routines: they should be checked against the C/Fortran source code, not least as the number of arguments is taken from the R code. For `.Call` and `.External` calls they will often suffice, but for `.C` and `.Fortran` calls the ‘void *’ arguments would ideally be replaced by the actual types. Otherwise declarations need to be included (they may exist earlier in that file if appending to a file, or in a header file which can be included in ‘init.c’).

The default value of `character_only` is appropriate when working on a package without any existing registration: `character_only = FALSE` can be used to suggest updates for a package which has been extended since registration. For the default value, if `.NAME` values are found which are not character strings (e.g. names or expressions) this is noted via a comment in the output.

Packages which used the earlier form of creating R objects for native symbols *via* additional arguments in a `useDynLib` directive will probably most easily be updated to use registration with `character_only = FALSE`.

If an entry point is used with different numbers of arguments in the package’s R code, an entry in the table (and optionally, a declaration) is made for each number, and a comment placed in the output. This needs to be resolved: only `.External` calls can have a variable number of arguments, which should be declared as `-1`.

A surprising number of CRAN packages had calls in R code to native routines not included in the package, which will lead to a ‘loading failed’ error during package installation when the registration C code is added.

Calls which do not name a routine such as `.Call(...)` will be silently ignored.

Value

None: the output is written to the connection `con`.

Extracting C/C++ prototypes

There are several tools available to extract function declarations from C or C++ code.

For C code one can use cproto (<https://invisible-island.net/cproto/cproto.html>; Windows executables are available), for example

```
cproto -I/path/to/R/include -e *.c
```

ctags (commonly distributed with the OS) covers C and C++, using something like

```
ctags -x *.c
```

to list all function usages. (The ‘Exuberant’ version allows a lot more control.)

Extracting Fortran prototypes

gfortran 9.2 and later can extract C prototypes for Fortran subroutines with a special flag:

```
gfortran -c -fc-prototypes-external file.f
```

although ironically not for functions declared `bind(C)`.

Note

This only examines the ‘R’ directory: it will not find e.g. `.Call` calls used directly in examples, tests *etc.*

Static code analysis is used to find the `.C` etc calls: it *will* find those in parts of the R code ‘commented out’ by inclusion in `if(FALSE) { ... }`. On the other hand, it will fail to find the entry points in constructs like

```
.Call(if(int) "rle_i" else "rle_d", i, force)
```

and does not know the value of variables in calls like

```
.Call (cfunction, ...)
.Call(..., PACKAGE="sparseLTSEigen")
```

(but if `character_only` is false, will extract the first as `"cfunction"`). Calls which have not been fully resolved will be noted *via* comments in the output file.

Call to entry points in other packages will be ignored if they have an explicit (character string) `PACKAGE` argument.

void R_init_splines(DllInfo *dll)
{
    R_registerRoutines(dll, NULL, CallEntries, NULL, NULL);
    R_useDynamicSymbols(dll, FALSE);
}

## End(Not run)
```

parseLatex

Experimental Functions to Work with LaTeX Code

Description

The `parseLatex` function parses LaTeX source, producing a structured object; `deparseLatex` reverses the process. The `latexToUtf8` function takes a LaTeX object, and processes a number of different macros to convert them into the corresponding UTF-8 characters.

Usage

```
parseLatex(text, filename = deparse1(substitute(text)),
           verbose = FALSE,
           verbatim = c("verbatim", "verbatim*",
                        "Sinput", "Soutput"),
           verb = "\\Sexpr")
deparseLatex(x, dropBraces = FALSE)
latexToUtf8(x)
```

Arguments

| | |
|-------------------------|------------------------------------------------------------------------------------------|
| <code>text</code> | A character vector containing LaTeX source code. |
| <code>filename</code> | A filename to use in syntax error messages. |
| <code>verbose</code> | If TRUE, print debug error messages. |
| <code>verbatim</code> | A character vector containing the names of LaTeX environments holding verbatim text. |
| <code>verb</code> | A character vector containing LaTeX macros that should be assumed to hold verbatim text. |
| <code>x</code> | A "LaTeX" object. |
| <code>dropBraces</code> | Drop unnecessary braces when displaying a "LaTeX" object. |

Details

The parser does not recognize all legal LaTeX code, only relatively simple examples. It does not associate arguments with macros, that needs to be done after parsing, with knowledge of the definitions of each macro. The main intention for this function is to process simple LaTeX code used in bibliographic references, not fully general LaTeX documents.

Verbose text is allowed in three forms: the `\verb` macro (with single character delimiters), environments whose names are listed in the `verbatim` argument, and other macros (with brace delimiters) whose names are listed in the `verb` argument.

Value

The `parseLatex()` function returns a recursive object of class "LaTeX". Each of the entries in this object will have a "latex_tag" attribute identifying its syntactic role.

The `deparseLatex()` function returns a single element character vector, possibly containing embedded newlines.

The `latexToUtf8()` function returns a modified version of the "LaTeX" object that was passed to it.

Author(s)

Duncan Murdoch

Examples

```
latex <- parseLatex("fran\\c{c}ais")
deparseLatex(latexToUtf8(latex))
```

 parse_Rd

Parse an Rd File

Description

This function reads an R documentation (Rd) file and parses it, for processing by other functions.

Usage

```
parse_Rd(file, srcfile = NULL, encoding = "unknown",
         verbose = FALSE, fragment = FALSE, warningCalls = TRUE,
         macros = file.path(R.home("share"), "Rd", "macros", "system.Rd"),
         permissive = FALSE)
## S3 method for class 'Rd'
print(x, deparse = FALSE, ...)
## S3 method for class 'Rd'
as.character(x, deparse = FALSE, ...)
```

Arguments

| | |
|--------------|---------------------------------------------------------------------------------------------------------------------|
| file | A filename or text-mode connection. At present filenames work best. |
| srcfile | NULL, or a "srcfile" object. See the 'Details' section. |
| encoding | Encoding to be assumed for input strings. |
| verbose | Logical indicating whether detailed parsing information should be printed. |
| fragment | Logical indicating whether file represents a complete Rd file, or a fragment. |
| warningCalls | Logical: should parser warnings include the call? |
| macros | Filename or environment from which to load additional macros, or a logical value. See the Details below. |
| permissive | Logical indicating that unrecognized macros should be treated as text with no warning. |
| x | An object of class Rd. |
| deparse | If TRUE, attempt to reinstate the escape characters so that the resulting characters will parse to the same object. |
| ... | Further arguments to be passed to or from other methods. |

Details

This function parses 'Rd' files according to the specification given in <https://developer.r-project.org/parseRd.pdf>.

It generates a warning for each parse error and attempts to continue parsing. In order to continue, it is generally necessary to drop some parts of the file, so such warnings should not be ignored.

Files without a marked encoding are by default assumed to be in the native encoding. An alternate default can be set using the encoding argument. All text in files is translated to the UTF-8 encoding in the parsed object.

As from R version 3.2.0, User-defined macros may be given in a separate file using ‘\newcommand’ or ‘\renewcommand’. An environment may also be given: it would be produced by `loadRdMacros`, `loadPkgRdMacros`, or by a previous call to `parse_Rd`. If a logical value is given, only the default built-in macros will be used; FALSE indicates that no “macros” attribute will be returned with the result.

The permissive argument allows text to be parsed that is not completely in Rd format. Typically it would be LaTeX code, used in an Rd fragment, e.g. in a `bibentry`. With `permissive = TRUE`, this will be passed through as plain text. Since `parse_Rd` doesn’t know how many arguments belong in LaTeX macros, it will guess based on the presence of braces after the macro; this is not infallible.

Value

`parse_Rd` returns an object of class “Rd”. The internal format of this object is subject to change. The `as.character()` and `print()` methods defined for the class return character vectors and print them, respectively.

Unless `macros = FALSE`, the object will have an attribute named “macros”, which is an environment containing the macros defined in file, in a format that can be used for further `parse_Rd` calls in the same session. It is not guaranteed to work if saved to a file and reloaded in a different session.

`Rd2HTML` for the converters that use the output of `parse_Rd()`.

pkg2HTML

Rd Converters

Description

Generate a single-page HTML reference manual from the Rd sources contained in an installed or source R package.

Usage

```
pkg2HTML(package, dir = NULL, lib.loc = NULL,
          outputEncoding = "UTF-8",
          stylesheet = file.path(R.home("doc"), "html", "R-nav.css"),
          hooks = list(pkg_href = function(pkg) sprintf("%s.html", pkg)),
          texmath = getOption("help.htmlmath"),
          prism = TRUE,
```

```

out = NULL,
toc_entry = c("title", "name"),
...,
Rhtml = FALSE,
mathjax_config = file.path(R.home("doc"), "html", "mathjax-config.js"),
include_description = TRUE)

```

Arguments

| | |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| package | a character string, typically giving the name of an installed package. Can also be a file path or URL pointing to a source tarball (this feature is experimental). |
| dir | character string giving the path to a directory containing an installed or source package. |
| lib.loc | a character vector describing the location of R library trees to search through, or NULL. Passed on to find.package and Rd_db . |
| outputEncoding | character string; see Rd2HTML . |
| stylesheet | character string giving URL containing CSS style information. |
| hooks | A list of functions controlling details of output. Currently the only component used is <code>pkg_href</code> , which is used to determine the output HTML file path given a package name as input. |
| texmath | character string controlling math rendering library to be used, either "katex" or "mathjax". The default is to use "katex", unless the package appears to use the mathjaxr package in at least one of its documentation files. The support for MathJax is experimental and may not work well. |
| prism | logical flag controlling code highlighting, as described in Rd2HTML . |
| out | a filename or connection object to which to write the output. The default <code>out = ""</code> is equivalent to <code>out = stdout()</code> . |
| toc_entry | Determines whether the entry for a help page in the table of contents is the name of the help page or its title. |
| ... | additional arguments, passed on to Rd2HTML . The <code>stages</code> argument, if specified, is passed on to Rd_db . |
| Rhtml | logical: whether the output is intended to be a Rhtml file that can be processed using knitr . If TRUE, the examples section is wrapped inside a rcode block. |
| mathjax_config | character string giving path of file containing configuration instructions for mathjax. Relevant only if <code>texmath = "mathjax"</code> . |
| include_description | logical flag indicating whether the output should begin with the contents of the DESCRIPTION file. |

Details

The `pkg2HTML` function is intended to produce a single-page HTML reference manual for a given package, with links to other packages. The URLs of links to external packages are controlled by the provided hooks.

The handling of `\Sexpr`-s are necessarily incomplete, but can be controlled to some extent by specifying the `stages` argument. Best results are likely for installed packages.

Value

The name of the output file (invisibly).

pkg2HTML("tools", out = tempfile(fileext = ".html")) |> browseURL()
```

pskill

Kill a Process

Description

pskill sends a signal to a process, usually to terminate it.

Usage

```
pskill(pid, signal = SIGTERM)
```

SIGHUP
SIGINT
SIGQUIT
SIGKILL
SIGTERM
SIGSTOP
SIGTSTP
SIGCHLD
SIGUSR1
SIGUSR2

Arguments

| | |
|--------|----------------------------------------------------------------------------------------|
| pid | positive integers: one or more process IDs as returned by Sys.getpid . |
| signal | integer, most often one of the symbolic constants. |

Details

Signals are a C99 concept, but only a small number are required to be supported (of those listed, only SIGINT and SIGTERM). They are much more widely used on POSIX operating systems (which should define all of those listed here), which also support a `kill` system call to send a signal to a process, most often to terminate it. Function `pskill` provides a wrapper: it silently ignores invalid values of its arguments, including zero or negative pids.

In normal use on a Unix-alike, `Ctrl-C` sends SIGINT, `Ctrl-\` sends SIGQUIT and `Ctrl-Z` sends SIGTSTP: that and SIGSTOP suspend a process which can be resumed by SIGCONT.

The signals are small integers, but the actual numeric values are not standardized (and most do differ between OSes). The `SIG*` objects contain the appropriate integer values for the current platform (or `NA_INTEGER_` if the signal is not defined).

Only SIGINT and SIGTERM will be defined on Windows, and `pskill` will always use the Windows system call `TerminateProcess`.

Value

A logical vector of the same length as `pid`, `TRUE` (for success) or `FALSE`, invisibly.

See Also

Package **parallel** has several means to launch child processes which record the process IDs.

[psnice](#)

Examples

```
## Not run:
pskill(c(237, 245), SIGKILL)

## End(Not run)
```

psnice

Get or Set the Priority (Niceness) of a Process

Description

Get or set the ‘niceness’ of the current process, or one or more other processes.

Usage

```
psnice(pid = Sys.getpid(), value = NA_integer_)
```

Arguments

| | |
|--------------------|-------------------------------------------------------------------------------------------------|
| <code>pid</code> | positive integers: the process IDs of one or more processes: defaults to the R session process. |
| <code>value</code> | The niceness to be set, or NA for an enquiry. |

Details

POSIX operating systems have a concept of process priorities, usually from 0 to 39 (or 40) with 20 being a normal priority and (somewhat confusingly) larger numeric values denoting lower priority. To add to the confusion, there is a ‘niceness’ value, the amount by which the priority numerically exceeds 20 (which can be negative). Processes with high niceness will receive less CPU time than those with normal priority. On some OSes, processes with niceness +19 are only run when the system would otherwise be idle.

On many OSes utilities such as `top` report the priority and not the niceness. Niceness is used by the utility `/usr/bin/renice`: `/usr/bin/nice` (and `/usr/bin/renice -n`) specifies an *increment* in niceness.

Only privileged users (usually super-users) can lower the niceness.

Windows has a slightly different concept of ‘priority classes’. We have mapped the idle priority to niceness 19, ‘below normal’ to 15, normal to 0, ‘above normal’ to -5 and ‘realtime’ to -10. Unlike Unix-alikes, a non-privileged user can increase the priority class on Windows (but using ‘realtime’ is inadvisable).

Value

An integer vector of *previous* niceness values, NA if unknown for any reason.

See Also

Various functions in package **parallel** create child processes whose priority may need to be changed. [pskill](#).

 QC

QC Checks for R Code and/or Documentation

Description

Functions for performing various quality control (QC) checks on R code and documentation, notably on R packages.

Usage

```
checkDocFiles (package, dir, lib.loc = NULL, chkInternal = NULL)
checkDocStyle (package, dir, lib.loc = NULL)
checkReplaceFuns(package, dir, lib.loc = NULL)
checkS3methods (package, dir, lib.loc = NULL)
checkRdContents (package, dir, lib.loc = NULL, chkInternal = NULL)

langElts
nonS3methods(package)
```

Arguments

| | |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>package</code> | a character string naming an installed package. |
| <code>dir</code> | a character string specifying the path to a package's root source (or <i>installed</i> in some cases) directory. This should contain the subdirectories 'R' (for R code) and 'man' with R documentation sources (in Rd format). Only used if <code>package</code> is not given. |
| <code>lib.loc</code> | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package. |
| <code>chkInternal</code> | logical indicating if Rd files marked with keyword <code>internal</code> should be checked as well. If NULL (default), these are checked "specially", ignoring missing documentation of arguments. |

Details

`checkDocFiles` checks, for all Rd files in a package, whether all arguments shown in the usage sections of the Rd file are documented in its arguments section. It also reports duplicated entries in the arguments section, and 'over-documented' arguments which are given in the arguments section but not in the usage.

`checkDocStyle` investigates how (S3) methods are shown in the usages of the Rd files in a package. It reports the methods shown by their full name rather than using the Rd `\method` markup for indicating S3 methods. Earlier versions of R also reported about methods shown along with their generic, which typically caused problems for the documentation of the primary argument in the generic and its methods. With `\method` now being expanded in a way that class information is preserved, joint documentation is no longer necessarily a problem. (The corresponding information is still contained in the object returned by `checkDocStyle`.)

`checkReplaceFuns` checks whether replacement functions or S3/S4 replacement methods in the package R code have their final argument named `value`.

`checkS3methods` checks whether all S3 methods defined in the package R code have all arguments of the corresponding generic, with positional arguments of the generics in the same positions for the method. As an exception, the first argument of a formula method *may* be called `formula` even if this is not the name used by the generic. The rules when `...` is involved are subtle: see the source code. Functions recognized as S3 generics are those with a call to `UseMethod` in their body, internal S3 generics (see [InternalMethods](#)), and S3 group generics (see [Math](#)). Possible dispatch under a different name is not taken into account. The generics are sought first in the given package, then (if given an installed package) in the package imports, and finally the namespace environment for the **base** package.

`checkRdContents()` checks Rd content, e.g., whether arguments of functions in the usage section have non empty descriptions.

`nonS3methods(package)` returns a [character](#) vector with the names of the functions in package which 'look' like S3 methods, but are not. Using `package = NULL` returns all known examples.

`langElts` is a character vector of names of "language elements" of R. These are implemented as "very primitive" functions (no argument list; `print()` as `.Primitive("name")`).

If using an installed package, the checks needing access to all R objects of the package will load the package (unless it is the **base** package), after possibly detaching an already loaded version of the package.

Value

The functions return objects of class the same as the respective function names containing the information about problems detected. There are `print` methods for nicely displaying the information contained in such objects.

Rcmd

R CMD *Interface*

Description

Invoke R CMD tools from within R.

Usage

```
Rcmd(args, ...)
```

Arguments

| | |
|-------------------|-----------------------------------------------------|
| <code>args</code> | a character vector of arguments to R CMD. |
| <code>...</code> | arguments to be passed to system2 . |

Details

Provides a portable convenience interface to the R CMD mechanism by invoking the corresponding system commands (using the version of R currently used) via [system2](#).

Value

See section “Value” in [system2](#).

Rd2HTML

Rd Converters

Description

These functions take the output of [parse_Rd\(\)](#), an Rd object, and produce a help page from it. As they are mainly intended for internal use, their interfaces are subject to change.

Usage

```
Rd2HTML(Rd, out = "", package = "", defines = .Platform$OS.type,
        Links = NULL, Links2 = NULL,
        stages = "render", outputEncoding = "UTF-8",
        dynamic = FALSE, no_links = FALSE, fragment = FALSE,
        stylesheet = if (dynamic) "/doc/html/R.css" else "R.css",
        texmath = getOption("help.htmlmath"),
        concordance = FALSE,
        standalone = TRUE,
        hooks = list(),
        toc = isTRUE(getOption("help.htmltoc")),
        Rhtml = FALSE,
        ...)
```

```
Rd2txt(Rd, out = "", package = "", defines = .Platform$OS.type,
        stages = "render", outputEncoding = "",
        fragment = FALSE, options, ...)
```

```
Rd2latex(Rd, out = "", defines = .Platform$OS.type,
        stages = "render", outputEncoding = "UTF-8",
        fragment = FALSE, ..., writeEncoding = TRUE,
        concordance = FALSE)
```

```
Rd2ex(Rd, out = "", defines = .Platform$OS.type,
        stages = "render", outputEncoding = "UTF-8",
        commentDontrun = TRUE, commentDonttest = FALSE, ...)
```

Arguments

| | |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>Rd</code> | a filename or Rd object to use as input. |
| <code>out</code> | a filename or connection object to which to write the output. The default <code>out = ""</code> is equivalent to <code>out = stdout()</code> . |
| <code>package</code> | the package to list in the output. |
| <code>defines</code> | string(s) to use in <code>#ifdef</code> tests. |
| <code>stages</code> | at which stage ("build", "install", or "render") should <code>\Sexpr</code> macros be executed? See the notes below. |
| <code>outputEncoding</code> | see the 'Encodings' section below. |
| <code>dynamic</code> | logical: set links for render-time resolution by dynamic help system. |
| <code>no_links</code> | logical: suppress hyperlinks to other help topics. Used by R CMD Rdconv . |
| <code>fragment</code> | logical: should fragments of Rd files be accepted? See the notes below. |
| <code>stylesheet</code> | character: a URL for a stylesheet to be used in the header of the HTML output page. |
| <code>texmath</code> | character: controls how mathematics in <code>\eqn</code> and <code>\deqn</code> commands are typeset in HTML output. Useful values are "katex" (default) and "mathjax" to use KaTeX or MathJax respectively, otherwise basic substitutions are used. May be |

| | |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| | ignored under certain circumstances, e.g., if the help page already uses macros from the mathjaxr package. |
| concordance | Whether concordance data should be embedded in the output file and attached to the return value. |
| standalone | logical: whether the output is intended to be a standalone HTML file. If FALSE, the header and footer are omitted, so that the output can be combined with other fragments. |
| hooks | A list of functions controlling details of output. Currently the only component used is <code>pkg_href</code> , which is used by <code>pkg2HTML</code> to determine the output HTML file path given a package name as input. |
| toc | logical: whether the HTML output should include a table of contents. Ignored unless <code>standalone = TRUE</code> . |
| Rhtml | logical: whether the output is intended to be a Rhtml file that can be processed using knitr . If TRUE, the examples section is wrapped inside a <code>rcode</code> block. |
| Links, Links2 | NULL or a named (by topics) character vector of links, as returned by findHTMLlinks . |
| options | An optional named list of options to pass to Rd2txt_options . |
| ... | additional parameters to pass to parse_Rd when <code>Rd</code> is a filename. |
| writeEncoding | should <code>\inputencoding</code> lines be written in the file for non-ASCII encodings? |
| commentDontrun | should <code>\dontrun</code> sections be commented out? |
| commentDonttest | should <code>\donttest</code> sections be commented out? |

Details

These functions convert help documents: `Rd2HTML` produces HTML, `Rd2txt` produces plain text, `Rd2latex` produces LaTeX. `Rd2ex` extracts the examples in the format used by [example](#) and R utilities.

Each of the functions accepts a filename for an Rd file, and will use [parse_Rd](#) to parse it before applying the conversions or checks.

The difference between arguments `Link` and `Link2` is that links are looked in them in turn, so lazy-evaluation can be used to only do a second-level search for links if required.

Before R 3.6.0, the default for `Rd2latex` was `outputEncoding = "ASCII"`, including using the second option of `\enc` markup, because \LaTeX versions did not provide enough coverage of UTF-8 glyphs for a long time.

`Rd2txt` will format text paragraphs to a width determined by `width`, with appropriate margins. The default is to be close to the rendering in versions of R < 2.10.0.

`Rd2txt` will use directional quotes (see [sQuote](#)) if option `"useFancyQuotes"` is true (usually the default, see [sQuote](#)) and the current encoding is UTF-8.

Various aspects of formatting by `Rd2txt` are controlled by the `options` argument, documented with the [Rd2txt_options](#) function. Changes made using options are temporary, those made with [Rd2txt_options](#) are persistent.

When `fragment = TRUE`, the Rd file will be rendered with no processing of `\Sexpr` elements or conditional defines using `\ifdef` or `\ifndef`. Normally a fragment represents text within a section,

but if the first element of the fragment is a section macro, the whole fragment will be rendered as a series of sections, without the usual sorting.

Value

These functions are executed mainly for the side effect of writing the converted help page. Their value is the name of the output file (invisibly). For `Rd2latex`, the output name is given an attribute `"latexEncoding"` giving the encoding of the file in a form suitable for use with the LaTeX `'inputenc'` package. For `Rd2HTML` with `standalone = FALSE`, an attribute `"info"` gives supplementary information such as the contents of the `name` and `title` fields. This is currently experimental, and the details are subject to change.

For `Rd2HTML` and `Rd2latex` with `concordance = TRUE`, a `"concordance"` attribute is added, containing an [Rconcordance](#) object.

Encodings

Rd files are normally intended to be rendered on a wide variety of systems, so care must be taken in the encoding of non-ASCII characters. In general, any such encoding should be declared using the `'encoding'` section for there to be any hope of correct rendering.

For output, the `outputEncoding` argument will be used: `outputEncoding = ""` will choose the native encoding for the current system.

If the text cannot be converted to the `outputEncoding`, byte substitution will be used (see [iconv](#)): `Rd2latex` and `Rd2ex` give a warning.

Note

The `\Sexpr` macro includes R code that will be executed at one of three times: *build* time (when a package's source code is built into a tarball), *install* time (when the package is installed or built into a binary package), and *render* time (when the man page is converted to a readable format).

For example, this man page was:

1. built on 2024-04-18 at 03:32:22,
2. installed on 2024-04-18 at 03:32:22, and
3. rendered on 2024-04-18 at 03:32:46.

Examples

```
## Simulate rendering of this (installed) page in HTML and text format
Rd <- Rd_db("tools")[[ "Rd2HTML.Rd" ]]

outfile <- tempfile(fileext = ".html")
Rd2HTML(Rd, outfile, package = "tools") |> browseURL()

outfile <- tempfile(fileext = ".txt")
Rd2txt(Rd, outfile, package = "tools") |> file.show()
```

Rd2txt_options

Set Formatting Options for Text Help

Description

This function sets various options for displaying text help.

Usage

```
Rd2txt_options(...)
```

Arguments

... A list containing named options, or options passed as individual named arguments. See below for currently defined ones.

Details

This function persistently sets various formatting options for the [Rd2txt](#) function which is used in displaying text format help. Currently defined options are:

width (default 80): The width of the output page.

minIndent (default 10): The minimum indent to use in a list.

extraIndent (default 4): The extra indent to use in each level of nested lists.

sectionIndent (default 5): The indent level for a section.

sectionExtra (default 2): The extra indentation for each nested section level.

itemBullet (default "`*`", with the asterisk replaced by a Unicode bullet in UTF-8 and most Windows locales): The symbol to use as a bullet in itemized lists.

enumFormat : A function to format item numbers in enumerated lists.

showURLs (default FALSE): Whether to show URLs when expanding `\href` tags.

code_quote (default TRUE): Whether to render `\code` and similar with single quotes.

underline_titles (default TRUE): Whether to render section titles with underlines (via backspacing).

Value

If called with no arguments, returns all option settings in a list. Otherwise, it changes the named settings and invisibly returns their previous values.

|-------|----------------------------------|

Description

Given two R output files, compute differences ignoring headers, footers and some other differences.

Usage

```
Rdiff(from, to, useDiff = FALSE, forEx = FALSE,
      nullPointers = TRUE, Log = FALSE)
```

Arguments

| | |
|--------------|--------------------------------------------------------------------------------------------------------------------------------|
| from, to | filepaths to be compared |
| useDiff | should diff be used to compare results? Overridden to false if the command is not available. |
| forEx | logical: extra pruning for ‘-Ex.Rout’ files to exclude headers and footers of examples, code and results for “--timings”, etc. |
| nullPointers | logical: should the displayed addresses of pointers be set to 0x00000000 before comparison? |
| Log | logical: should the returned value include a log of differences found? |

Details

The R startup banner and any timing information from R CMD BATCH are removed from both files, together with lines about loading packages. UTF-8 fancy quotes (see [sQuote](#)) and on Windows, Windows' so-called 'smart quotes', are mapped to a simple quote. Addresses of environments, compiled bytecode and other exotic types expressed as hex addresses (e.g., '<environment: 0x12345678>') are mapped to 0x00000000. The files are then compared line-by-line. If there are the same number of lines and useDiff is false, a simple diff -b -like display of differences is printed (which ignores trailing spaces and differences in numbers of consecutive spaces), otherwise diff -bw is called on the edited files. (This tries to ignore all differences in whitespace: note that flag '-w' is not required by POSIX but is supported by GNU, Solaris and FreeBSD versions – macOS uses an old GNU version.)

There is limited support for comparing PDF files produced by pdf(compress = FALSE), mainly for use in make check – this requires a diff command and useDiff = TRUE.

Mainly for use in examples and tests, text from marker '> ## IGNORE_RDIFF_BEGIN' up to (but not including) '> ## IGNORE_RDIFF_END' is ignored.

Value

If Log is true, a list with components status (see below) and out, a character vector of descriptions of differences, possibly of zero length.

Otherwise, a status indicator (invisibly), 0L if and only if no differences were found.

See Also

The shell script run as R CMD Rdiff, which uses useDiff = TRUE.

Rdindex

Generate Index from Rd Files

Description

Print a 2-column index table with names and titles from given R documentation files to a given output file or connection. The titles are nicely formatted between two column positions (typically 25 and 72, respectively).

Usage

```
Rdindex(RdFiles, outFile = "", type = NULL,
        width = 0.9 * getOption("width"), indent = NULL)
```

Arguments

RdFiles a character vector specifying the Rd files to be used for creating the index, either by giving the paths to the files, or the path to a single directory with the sources of a package.

| | |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| outFile | a connection, or a character string naming the output file to print to. "" (the default) indicates output to the console. |
| type | a character string giving the documentation type of the Rd files to be included in the index, or NULL (the default). The type of an Rd file is typically specified via the \docType tag; if type is "data", Rd files whose <i>only</i> keyword is datasets are included as well. |
| width | a positive integer giving the target column for wrapping lines in the output. |
| indent | a positive integer specifying the indentation of the second column. Must not be greater than width/2, and defaults to width/3. |

Details

If a name is not a valid alias, the first alias (or the empty string if there is none) is used instead.

| | |
|--------------|----------------------------------|
| RdTextFilter | <i>Select Text in an Rd File</i> |
|--------------|----------------------------------|

Description

This function blanks out all non-text in an Rd file, for spell checking or other uses.

Usage

```
RdTextFilter(ifile, encoding = "unknown", keepSpacing = TRUE,
             drop = character(), keep = character(),
             macros = file.path(R.home("share"), "Rd", "macros", "system.Rd"))
```

Arguments

| | |
|-------------|--------------------------------------------------------------------------------------------------------|
| ifile | An input file specified as a filename or connection, or an "Rd" object from parse_Rd . |
| encoding | An encoding name to pass to parse_Rd . |
| keepSpacing | Whether to try to leave the text in the same lines and columns as in the original file. |
| drop | Additional sections of the Rd to drop. |
| keep | Sections of the Rd file to keep. |
| macros | Macro definitions to assume when parsing. See parse_Rd . |

Details

This function parses the Rd file, then walks through it, element by element. Items with tag "TEXT" are kept in the same position as they appeared in the original file, while other parts of the file are replaced with blanks, so a spell checker such as [aspell](#) can check only the text and report the position in the original file. (If keepSpacing is FALSE, blank filling will not occur, and text will not be output in its original location.)

By default, the tags `\S3method`, `\S4method`, `\command`, `\docType`, `\email`, `\encoding`, `\file`, `\keyword`, `\link`, `\linkS4class`, `\method`, `\pkg`, and `\var` are skipped. Additional tags can be skipped by listing them in the `drop` argument; listing tags in the `keep` argument will stop them from being skipped. It is also possible to keep any of the `c("RCODE", "COMMENT", "VERB")` tags, which correspond to R-like code, comments, and verbatim text respectively, or to drop `"TEXT"`.

Value

A character vector which if written to a file, one element per line, would duplicate the text elements of the original Rd file.

Note

The filter attempts to merge text elements into single words when markup in the Rd file is used to highlight just the start of a word.

Author(s)

Duncan Murdoch

See Also

[aspell](#), for which this is an acceptable filter.

Rdutils

Rd Utilities

Description

Utilities for computing on the information in Rd objects.

Usage

```
Rd_db(package, dir, lib.loc = NULL, stages = "build")
```

Arguments

| | |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>package</code> | a character string naming an installed package. |
| <code>dir</code> | a character string specifying the path to a package's root source directory. This should contain the subdirectory 'man' with R documentation sources (in Rd format). Only used if <code>package</code> is not given. |
| <code>lib.loc</code> | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. The specified library trees are used to search for package. |
| <code>stages</code> | if <code>dir</code> is specified and the database is being built from source, which stages of <code>\Sexpr</code> processing should be processed? |

Details

Rd_db builds a simple database of all Rd objects in a package, as a list of the results of running [parse_Rd](#) on the Rd source files in the package and processing platform conditionals and some \Sexpr macros.

See Also

[parse_Rd](#)

Examples

```
## Build the Rd db for the (installed) base package.
db <- Rd_db("base")

## Keyword metadata per Rd object.
keywords <- lapply(db, tools:::Rd_get_metadata, "keyword")
## Tabulate the keyword entries.
kw_table <- sort(table(unlist(keywords)))
## The 5 most frequent ones:
rev(kw_table)[1 : 5]
## The "most informative" ones:
kw_table[kw_table == 1]
```

```
## Concept metadata per Rd file.
concepts <- lapply(db, tools:::Rd_get_metadata, "concept")
## How many files already have \concept metadata?
sum(sapply(concepts, length) > 0)
## How many concept entries altogether?
length(unlist(concepts))
```

read.00Index

Read 00Index-style Files

Description

Read item/description information from ‘00Index’-like files. Such files are description lists rendered in tabular form, and currently used for the ‘INDEX’ and ‘demo/00Index’ files of add-on packages.

Usage

```
read.00Index(file)
```

Arguments

| | |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| file | the name of a file to read data values from. If the specified file is "", then input is taken from the keyboard (in this case input can be terminated by a blank line). Alternatively, file can be a connection , which will be opened if necessary, and if so closed at the end of the function call. |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Value

A character matrix with 2 columns named "Item" and "Description" which hold the items and descriptions.

See Also

[formatDL](#) for the inverse operation of creating a 00Index-style file from items and their descriptions.

showNonASCII

Pick Out Non-ASCII Characters

Description

This function prints elements of a character vector which contain non-ASCII bytes, printing such bytes as a escape like '<fc>'.

Usage

```
showNonASCII(x)
```

```
showNonASCIIfile(file)
```

Arguments

| | |
|------|---------------------|
| x | a character vector. |
| file | path to a file. |

Details

This was originally written to help detect non-portable text in files in packages.

It prints all elements of x which contain non-ASCII characters, preceded by the element number and with non-ASCII bytes highlighted *via* [iconv](#)(sub = "byte").

However, this rendering depends on [iconv](#)(to = "ASCII") failing to convert, and macOS 14 no longer does so reliably so for example permille ('&u2030') is rendered as o/oo.

Value

The elements of x containing non-ASCII characters will be returned invisibly.

Examples

```
out <- c(
  "fran\xE7ais: test of showNonASCII():",
  "\\details{",
  "  This is a good line",
  "  This has an \xfcm\aut in it.",
  "  OK again.",
  "}")
f <- tempfile()
cat(out, file = f, sep = "\n")

showNonASCIIfile(f)
unlink(f)
```

| | |
|------------------|-------------------------------------------|
| startDynamicHelp | <i>Start the Dynamic HTML Help System</i> |
|------------------|-------------------------------------------|

Description

This function starts the internal help server, so that HTML help pages are rendered when requested.

Usage

```
startDynamicHelp(start = TRUE)
```

Arguments

| | |
|-------|----------------------------------------------------------------------------------------------------------------------|
| start | logical: whether to start or shut down the dynamic help system. If NA, the server is started if not already running. |
|-------|----------------------------------------------------------------------------------------------------------------------|

Details

This function starts the internal HTTP server, which runs on the loopback interface ('127.0.0.1'). If `options("help.ports")` is set to a vector of non-zero integer values, `startDynamicHelp` will try those ports in order; otherwise, it tries up to 10 random ports to find one not in use. It can be disabled by setting the environment variable `R_DISABLE_HTTPD` to a non-empty value or `options("help.ports")` to `0`.

`startDynamicHelp` is called by functions that need to use the server, so would rarely be called directly by a user.

Note that `options(help_type = "html")` must be set to actually make use of HTML help, although it might be the default for an R installation.

If the server cannot be started or is disabled, `help.start` will be unavailable and requests for HTML help will give text help (with a warning).

The browser in use does need to be able to connect to the loopback interface: occasionally it is set to use a proxy for HTTP on all interfaces, which will not work – the solution is to add an exception for '127.0.0.1'.

Value

The chosen port number is returned invisibly (which will be 0 if the server has been stopped).

See Also

[help.start](#) and [help](#)(help_type = "html") will attempt to start the HTTP server if required. [Rd2HTML](#) is used to render the package help pages.

SweaveTeXFilter

Strip R Code out of Sweave File

Description

This function blanks out code chunks and Noweb markup in an Sweave input file, for spell checking or other uses.

Usage

```
SweaveTeXFilter(ifile, encoding = "unknown")
```

Arguments

| | |
|----------|------------------------------------------------------|
| ifile | Input file or connection. |
| encoding | Text encoding to pass to readLines . |

Details

This function blanks out all Noweb markup and code chunks from an Sweave input file, leaving behind the LaTeX source, so that a LaTeX-aware spelling checker can check it and report errors in their original locations.

Value

A character vector which if written to a file, one element per line, would duplicate the text elements of the original Sweave input file.

Author(s)

Duncan Murdoch

See Also

[aspell](#), for which this is used with filter = "Sweave".

testInstalledPackage *Test Installed Packages*

Description

These functions allow an installed package to be tested, or all base and recommended packages.

Usage

```
testInstalledPackage(pkg, lib.loc = NULL, outDir = ".",
                    types = c("examples", "tests", "vignettes"),
                    srcdir = NULL, Ropts = "", ...)

testInstalledPackages(outDir = ".", errorsAreFatal = TRUE,
                    scope = c("both", "base", "recommended"),
                    types = c("examples", "tests", "vignettes"),
                    srcdir = NULL, Ropts = "", ...)

testInstalledBasic(scope = c("basic", "devel", "both", "internet", "all"),
                  outDir = file.path(R.home(), "tests"),
                  testSrcdir = getTestSrcdir(outDir))

standard_package_names()
```

Arguments

| | |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pkg | name of an installed package. |
| lib.loc | library path(s) in which to look for the package. See library . |
| outDir | the directory into which to write the output files: this should already exist. The default, "." is the current working directory. Often a subdirectory is preferable. |
| types | type(s) of tests to be done. |
| srcdir | Optional directory to look for .save files. |
| Ropts | Additional options such as '-d valgrind' to be passed to R CMD BATCH when running examples or tests. |
| errorsAreFatal | logical: should testing terminate at the first error? |
| scope | a string indicating which set(s) should be tested. "both" includes "basic" and "devel"; "all" adds "internet". Can be abbreviated. |
| ... | additional arguments use when preparing the files to be run, e.g. commentDontrun and commentDonttest. |
| testSrcdir | optional directory where the test R scripts are found. |

Details

The `testInstalledPackage{s}()` tests depend on having the package example files installed (which is the default).

If package-specific tests are found in a ‘tests’ directory they can be tested: these are not installed by default, but will be if `R CMD INSTALL --install-tests` was used. Finally, the R code in any vignettes can be extracted and tested.

The package-specific tests are run in a ‘pkg-tests’ subdirectory of ‘outDir’, and leave their output there.

`testInstalledBasic` runs the basic tests, if installed or inside `testSrcdir`. This should be run with `LC_COLLATE=C` set: the function tries to set this but it may not work on all OSes. For non-English locales it may be desirable to set environment variables `LANGUAGE` to ‘en’ and `LC_TIME` to ‘C’ to reduce the number of differences from reference results.

Except on Windows, if the environment variable `TEST_MC_CORES` is set to an integer greater than one, `testInstalledPackages` will run the package tests in parallel using its value as the maximum number of parallel processes.

The package-specific tests for the base and recommended packages are not normally installed, but make `install-tests` is provided to do so (as well as the basic tests).

Value

Invisibly `0L` for success, `1L` for failure.

`standard_package_names()` returns a [list](#) with components named

`base` a character vector with the ‘base’ package names.

`recommended` a character vector with the ‘Recommended’ package names in historical order.

Examples

```
str(stPkgs <- standard_package_names())

## consistency of packageDescription and standard_package_names :
(pNms <- unlist(stPkgs, FALSE))
(prio <- sapply(as.vector(pNms), packageDescription, fields = "Priority"))
stopifnot(identical(unname(prio),
                     sub("[0-9]+$", '', names(pNms))))
```

Description

Run `latex/pdflatex`, `makeindex` and `bibtex` until all cross-references are resolved to create a DVI or a PDF file.

Usage

```
texi2dvi(file, pdf = FALSE, clean = FALSE, quiet = TRUE,
         texi2dvi = getOption("texi2dvi"),
         texinputs = NULL, index = TRUE)

texi2pdf(file, clean = FALSE, quiet = TRUE,
         texi2dvi = getOption("texi2dvi"),
         texinputs = NULL, index = TRUE)
```

Arguments

| | |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| file | character string. Name of the LaTeX source file. |
| pdf | logical. If TRUE, a PDF file is produced instead of the default DVI file (texi2dvi command line option ‘--pdf’). |
| clean | logical. If TRUE, all auxiliary files created during the conversion are removed. |
| quiet | logical. No output unless an error occurs. |
| texi2dvi | character string (or NULL). Script or program used to compile a TeX file to DVI or PDF. The default (selected by "" or "texi2dvi" or NULL) is to look for a program or script named texi2dvi on the path and otherwise emulate the script with system2 calls (which can be selected by the value "emulation"). See also ‘Details’. |
| texinputs | NULL or a character vector of paths to add to the LaTeX and BibTeX input search paths. |
| index | logical: should indices be prepared? |

Details

texi2pdf is a wrapper for the common case of texi2dvi(pdf = TRUE).

Despite the name, this is used in R to compile LaTeX files, specifically those generated from vignettes and by the [Rd2pdf](#) script (used for package reference manuals). It ensures that the ‘[R_HOME](#)/share/texmf’ directory is in the TEXINPUTS path, so R style files such as ‘Sweave.sty’ and ‘Rd.sty’ will be found. The TeX search path used is first the existing TEXINPUTS setting (or the current directory if unset), then elements of argument texinputs, then ‘[R_HOME](#)/share/texmf’ and finally the default path. Analogous changes are made to BIBINPUTS and BSTINPUTS settings.

The default option for texi2dvi is set from environment variable R_TEXI2DVICMD, and the default for that is set from environment variable TEXI2DVI or if that is unset, from a value chosen when R is configured.

A shell script texi2dvi is part of GNU’s **texinfo**. Several issues have been seen with released versions, so if yours does not work correctly try R_TEXI2DVICMD=emulation.

Occasionally indices contain special characters which cause indexing to fail (particularly when using the ‘hyperref’ LaTeX package) even on valid input. The argument index = FALSE is provided to allow package manuals to be made when this happens: it uses emulation.

Value

Invisible NULL. Used for the side effect of creating a DVI or PDF file in the current working directory (and maybe other files, especially if clean = FALSE).

Note

There are various versions of the `texi2dvi` script on Unix-alikes and quite a number of bugs have been seen, some of which this R wrapper works around.

One that was present with `texi2dvi` version 4.8 (as supplied by macOS) is that it will not work correctly for paths which contain spaces, nor if the absolute path to a file would contain spaces.

The three possible approaches all have their quirks. For example the Unix-alike `texi2dvi` script removes ancillary files that already exist but the other two approaches do not (and may get confused by such files).

Where supported (`texi2dvi` 5.0 and later; `texify.exe` from MiKTeX), option `'--max-iterations=20'` is used to avoid infinite retries.

The emulation mode supports `quiet = TRUE` from R 3.2.3 only. Currently `clean = TRUE` only cleans up in this mode if the conversion was successful—this gives users a chance to examine log files in the event of error.

All the approaches should respect the values of environment variables `LATEX`, `PDFLATEX`, `MAKEINDEX` and `BIBTEX` for the full paths to the corresponding commands.

Author(s)

Originally Achim Zeileis but largely rewritten by R-core.

toHTML

Display an Object in HTML

Description

This generic function generates a complete HTML page from an object.

Usage

```
toHTML(x, ...)
## S3 method for class 'packageIQR'
toHTML(x, ...)
## S3 method for class 'news_db'
toHTML(x, ...)
```

Arguments

| | |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code> | An object to display. |
| <code>...</code> | Optional parameters for methods; the <code>"packageIQR"</code> and <code>"news_db"</code> methods pass these to HTMLheader . |

Value

A character vector to display the object `x`. The `"packageIQR"` method is designed to display lists in the R help system.

See Also[HTMLheader](#)**Examples**

```
cat(toHTML(demo(package = "base")), sep = "\n")
```

tools-deprecated

*Deprecated Objects in Package **tools*****Description**

(Currently none)

The functions or variables listed here are provided for compatibility with older versions of R only, and may be defunct as soon as of the next release.

See Also[Deprecated, Defunct](#)

toRd

*Generic Function to Convert Object to a Fragment of Rd Code***Description**

Methods for this function render their associated classes as a fragment of Rd code, which can then be rendered into text, HTML, or LaTeX.

Usage

```
toRd(obj, ...)
## S3 method for class 'bibentry'
toRd(obj, style = NULL, ...)
```

Arguments

| | |
|--------------------|-----------------------------------------------------------------------|
| <code>obj</code> | The object to be rendered. |
| <code>style</code> | The style to be used in converting a bibentry object. |
| <code>...</code> | Additional arguments used by methods. |

Details

See [bibstyle](#) for a discussion of styles. The default `style = NULL` value gives the default style.

Value

Returns a character vector containing a fragment of Rd code that could be parsed and rendered. The default method converts `obj` to mode `character`, then escapes any Rd markup within it. The `bibentry` method converts an object of that class to markup appropriate for use in a bibliography.

toTitleCase

Convert Titles to Title Case

Description

Convert a character vector to title case, especially package titles.

Usage

```
toTitleCase(text)
```

Arguments

`text` a character vector.

Details

This is intended for English text only.

No definition of ‘title case’ is universally accepted: all agree that ‘principal’ words are capitalized and common words like ‘for’ are not, but not which words fall into each category.

Generally words in all capitals are left alone: this implementation knows about conventional mixed-case words such as ‘LaTeX’ and ‘OpenBUGS’ and a few technical terms which are not usually capitalized such as ‘jar’ and ‘xls’. However, unknown technical terms will be capitalized unless they are single words enclosed in single quotes: names of packages and libraries should be quoted in titles.

Value

A character vector of the same length as `text`, without names.

undoc*Find Undocumented Objects*

Description

Finds the objects in a package which are undocumented, in the sense that they are visible to the user (or data objects or S4 classes provided by the package), but no documentation entry exists.

Usage

```
undoc(package, dir, lib.loc = NULL)
```

Arguments

| | |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>package</code> | a character string naming an installed package. |
| <code>dir</code> | a character string specifying the path to a package's root source directory. This must contain the subdirectory 'man' with R documentation sources (in Rd format), and at least one of the 'R' or 'data' subdirectories with R code or data objects, respectively. |
| <code>lib.loc</code> | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package. |

Details

This function is useful for package maintainers mostly. In principle, *all* user-level R objects should be documented.

The **base** package is special as it contains the primitives and these do not have definitions available at code level. We provide equivalent closures in environments `.ArgsEnv` and `.GenericArgsEnv` in the **base** package that are used for various purposes: `undoc("base")` checks that all the primitives that are not language constructs are prototyped in those environments and no others are.

Value

An object of class "undoc" which is a list of character vectors containing the names of the undocumented objects split according to documentation type.

There is a `print` method for nicely displaying the information contained in such objects.

See Also

[codoc](#), [QC](#)

Examples

```
undoc("tools")           # Undocumented objects in 'tools'
```

| | |
|-----------------|---------------------------------------|
| update_PACKAGES | <i>Update Existing PACKAGES Files</i> |
|-----------------|---------------------------------------|

Description

Update an existing repository by reading the PACKAGES file, retaining entries which are still valid, removing entries which are no longer valid, and only processing built package tarballs which do not match existing entries.

update_PACKAGES can be much faster than [write_PACKAGES](#) for small-moderate changes to large repository indexes, particularly in non-strict mode (see Details).

Usage

```
update_PACKAGES(dir = ".", fields = NULL, type = c("source",
  "mac.binary", "win.binary"), verbose.level = as.integer(dryrun),
  latestOnly = TRUE, addFiles = FALSE, rds_compress = "xz",
  strict = TRUE, dryrun = FALSE)
```

Arguments

| | |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dir | see write_PACKAGES . |
| fields | see write_PACKAGES . |
| type | see write_PACKAGES . |
| verbose.level | one of {0, 1, 2}, the level of informative messages displayed throughout the process. Defaults to 0 if dryrun is FALSE (the default) and 1 otherwise. See Details for more information. |
| latestOnly | see write_PACKAGES . |
| addFiles | see write_PACKAGES . |
| rds_compress | see write_PACKAGES . |
| strict | logical. Should “strict mode” be used when checking existing PACKAGES entries. See Details. Defaults to TRUE. |
| dryrun | logical. Should the updates to existing PACKAGES files be computed but NOT applied. Defaults to FALSE. |

Details

Throughout this section, *package tarball* is defined to mean any archive file in `dir` whose name can be interpreted as ‘*package_version.ext*’ – with *ext* the appropriate extension for built packages of type `type` – (or that is pointed to by the `File` field of an existing PACKAGES entry). *Novel package tarballs* are those which do not match an existing PACKAGES file entry.

update_PACKAGES calls directly down to [write_PACKAGES](#) with a warning (and thus all package tarballs will be processed), if any of the following conditions hold:

- type is “win.binary” and strict is TRUE (no MD5 checksums are included in win.binary PACKAGES files)

- No PACKAGES file exists under `dir`
- A PACKAGES file exists under `dir` but is empty
- `fields` is not NULL and one or more specified fields are not present in the existing PACKAGES file

`update_PACKAGES` avoids (re)processing package tarballs in cases where a PACKAGES file entry already exists and appears to remain valid. The logic for detecting still-valid entries is as follows:

Any package tarball which was last modified more recently than the existing PACKAGES file is considered novel; existing PACKAGES entries appearing to correspond to such tarballs are *always* considered stale and replaced by newly generated ones. Similarly, all PACKAGES entries that do not correspond to any package tarball found in `dir` are considered invalid and are excluded from the resulting updated PACKAGES files.

When `strict` is TRUE, PACKAGES entries that match a package tarball (by package name and version) are confirmed via MD5 checksum; only those that pass are retained as valid. All novel package tarballs are fully processed by the standard machinery underlying `write_PACKAGES` and the resulting entries are added. Finally, if `latestOnly` is TRUE, package-version pruning is performed across the entries.

When `strict` is FALSE, package tarballs are assumed to encode correct metadata in their filenames. PACKAGES entries which appear to match a package tarball are retained as valid (No MD5 checksum testing occurs). If `latestOnly` is TRUE, package-version pruning is performed across the full set of retained entries and novel package tarballs *before* the processing of the novel tarballs, at significant computational and time savings in some situations. After the optional pruning, any relevant novel package tarballs are processed via the standard machinery and added to the set of retained entries.

In both cases, after the above process concludes, entries are sorted alphabetically by the string concatenation of Package and Version. This should match the entry order `write_PACKAGES` outputs.

The fields within the entries are ordered as follows: canonical fields - i.e., those appearing as columns when `available.packages` is called on a CRAN mirror - appear first in their canonical order, followed by any non-canonical fields.

After entry and field reordering, the final database of PACKAGES entries is written to all three PACKAGES files, overwriting the existing versions.

When `verbose.level` is 0, no extra messages are displayed to the user. When it is 1, detailed information about what is happening is conveyed via messages, but underlying machinery from `write_PACKAGES` is invoked with `verbose = FALSE`. Behavior when `verbose.level` is 2 is identical to `verbose.level` 1 with the exception that underlying machinery from `write_PACKAGES` is invoked with `verbose = TRUE`, which will individually list every processed tarball.

Note

While both `strict` and non-`strict` modes can offer speedups when updating small percentages of large repositories, non-`strict` mode is *much* faster and is recommended in situations where the assumption it makes about tarballs' filenames encoding accurate information is safe.

Note

Users should expect significantly smaller speedups over `write_PACKAGES` in the `type == "win.binary"` case on at least some operating systems. This is due to `write_PACKAGES` being significantly faster in this context, rather than `update_PACKAGES` being slower.

  type = "win.binary") # on Linux
update_PACKAGES("/pub/RWin/bin/windows/contrib/2.9",
  type = "win.binary") # on Linux

## End(Not run)
```

update_pkg_po

Prepare Translations for a Package

Description

Prepare the ‘po’ directory of a package and optionally compile and install the translations.

Usage

```
update_pkg_po(pkgdir, pkg = NULL, version = NULL,
  pot_make = TRUE, mo_make = TRUE,
  verbose = getOption("verbose"),
  mergeOpts = "", copyright, bugs)
```

Arguments

| | |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pkgdir | The path to the package directory. |
| pkg | The package name: if NULL it is read from the package’s ‘DESCRIPTION’ file. |
| version | The package version: if NULL it is read from the package’s ‘DESCRIPTION’ file. |
| pot_make, mo_make | logicals indicating if a new ‘*.pot’ file or new binary translations ‘*.mo’ should be (re)created. |
| verbose | logical indicating if extra information about the updating process should be printed to the console. |
| mergeOpts | a string, by default empty, of space-separated options to msgmerge in addition to “--update”. Since R 4.2.0, “--no-wrap” is used when called from <code>file.path(R.home("po"), "Makefile")</code> . |

copyright, bugs optional character strings for the ‘Copyright’ and ‘Report-Msgid-Bugs-To’ details in the template files.

Details

This performs a series of steps to prepare or update messages in the package.

- If the package sources do not already have a ‘po’ directory, one is created.
- `xgettext2pot` is called to create/update a file ‘po/R-*pkgname*.pot’ containing the translatable messages in the package.
- All existing files in directory po with names ‘R-*lang*.po’ are updated from ‘R-*pkgname*.pot’, `checkPoFile` is called on the updated file, and if there are no problems the file is compiled and installed under ‘inst/po’.
- In a UTF-8 locale, a ‘translation’ ‘R-en@quot.pot’ is created with UTF-8 directional quotes, compiled and installed under ‘inst/po’.
- The remaining steps are done only if file ‘po/*pkgname*.pot’ already exists. The ‘src/*.{c,cc,cpp,m,mm}’ files in the package are examined to create a file ‘po/*pkgname*.pot’ containing the translatable messages in the C/C++ files. If there is a src/windows directory, files within it are also examined.
- All existing files in directory po with names ‘*lang*.po’ are updated from ‘*pkgname*.pot’, `checkPoFile` is called on the updated file, and if there are no problems the file is compiled and installed under ‘inst/po’.
- In a UTF-8 locale, a ‘translation’ ‘en@quot.pot’ is created with UTF-8 directional quotes, compiled and installed under ‘inst/po’.

Note that C/C++ messages are not automatically prepared for translation as they need to be explicitly marked for translation in the source files. Once that has been done, create an empty file ‘po/*pkgname*.pot’ in the package sources and run this function again.

pkg = "base" is special (and for use by R developers only): the C files are not in the package directory but in the main sources.

System requirements

This function requires the following tools from the GNU gettext-tools: `xgettext`, `msgmerge`, `msgfmt`, `msginit` and `msgconv`. These are part of most Linux distributions and easily compiled from the sources on Unix-alikes (including macOS). Pre-compiled versions for Windows are available in <https://www.stats.ox.ac.uk/pub/Rtools/goodies/gettext-tools.zip>.

It will probably not work correctly for en@quot translations except in a UTF-8 locale, so these are skipped elsewhere.

`xgettext2pot`.

userdir

*R User Directories***Description**

Directories for storing R-related user-specific data, configuration and cache files.

Usage

```
R_user_dir(package, which = c("data", "config", "cache"))
```

Arguments

| | |
|---------|------------------------------------------------------------------------------------|
| package | a character string giving the name of an R package |
| which | a character string indicating the kind of file(s) of interest. Can be abbreviated. |

Details

For desktop environments using X Windows, the freedesktop.org project (formerly X Desktop Group, XDG) developed the XDG Base Directory Specification (<https://specifications.freedesktop.org/basedir-spec>) for standardizing the location where certain files should be placed. CRAN package **rappdirs** provides these general locations with appropriate values for all platforms for which R is available.

R_user_dir specializes the general mechanism to R package specific locations for user files, by providing package specific subdirectories inside a ‘R’ subdirectory inside the “base” directories appropriate for user-specific data, configuration and cache files (see the examples), with the intent that packages will not interfere if they work within their respective subdirectories.

The locations of these base directories can be customized via the specific environment variables R_USER_DATA_DIR, R_USER_CONFIG_DIR and R_USER_CACHE_DIR. If these are not set, the general XDG-style environment variables XDG_DATA_HOME, XDG_CONFIG_HOME and XDG_CACHE_HOME are used if set, and otherwise, defaults appropriate for the R platform in use are employed.

Examples

```
R_user_dir("F00", "cache")

## Create one, platform agnostically, must work if <normal> :
(Rdb <- R_user_dir("base"))
if(newD <- !dir.exists(Rdb)) # should work user specifically:
  newD <- dir.create(Rdb, recursive=TRUE)
dir(Rdb) # typically empty
if(newD) unlink(Rdb) # cleaning up

list.files(R_user_dir("grid"), full.names = TRUE)
```

| | |
|----------------|------------------------------------------------|
| vignetteEngine | <i>Set or Get a Vignette Processing Engine</i> |
|----------------|------------------------------------------------|

Description

Vignettes are normally processed by [Sweave](#), but package writers may choose to use a different engine (e.g., one provided by the [knitr](#), [noweb](#) or [R.rsp](#) packages). This function is used by those packages to register their engines, and internally by R to retrieve them.

Usage

```
vignetteEngine(name, weave, tangle, pattern = NULL,
               package = NULL, aspell = list())
```

Arguments

| | |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| name | the name of the engine. |
| weave | a function to convert vignette source files to PDF/HTML or intermediate LaTeX output. |
| tangle | a function to convert vignette source files to R code. |
| pattern | a regular expression pattern for the filenames handled by this engine, or NULL for the default pattern. |
| package | the package registering the engine. By default, this is the package calling vignetteEngine. |
| aspell | a list with element names filter and/or control giving the respective arguments to be used when spell checking the text in the vignette source file with aspell . |

Details

If weave is missing, vignetteEngine will return the currently registered engine matching name and package.

If weave is NULL, the specified engine will be deleted.

Other settings define a new engine. The weave and tangle functions must be defined with argument lists compatible with `function(file, ...)`. Currently the ... arguments may include logical argument quiet and character argument encoding; others may be added in future. These are described in the documentation for [Sweave](#) and [Stangle](#).

The weave and tangle functions should return the filename of the output file that has been produced. Currently the weave function, when operating on a file named '<name><pattern>' must produce a file named '<name>[.](tex|pdf|html)'. The '.tex' files will be processed by pdf_latex to produce '.pdf' output for display to the user; the others will be displayed as produced. The tangle function must produce a file named '<name>[.][rRsS]' containing the executable R code from the vignette. The tangle function may support a split = TRUE argument, and then it should produce files named '<name>.*[.][rRsS]'.

The pattern argument gives a regular expression to match the extensions of files which are to be processed as vignette input files. If set to NULL, the default pattern "[.][RrSs](nw|tex)\$" is used.

Value

If the engine is being deleted, NULL. Otherwise a list containing components

| | |
|---------|--------------------------------------|
| name | The name of the engine |
| package | The name of its package |
| pattern | The pattern for vignette input files |
| weave | The weave function |
| tangle | The tangle function |

Author(s)

Duncan Murdoch and Henrik Bengtsson.

Examples

```
str(vignetteEngine("Sweave"))
```

| | |
|--------------|-------------------------------------------|
| vignetteInfo | <i>Basic Information about a Vignette</i> |
|--------------|-------------------------------------------|

Description

Extract metadata from a vignette source file.

Usage

```
vignetteInfo(file)
```

Arguments

file file name of the vignette.

Value

A [list](#) with the following [character](#) components:

| | |
|----------|---------------------------------------------------------------------------------|
| file | the basename of the file. |
| title | the vignette title from ‘\VignetteIndexEntry’, possibly an empty string. |
| depends | a vector of package dependencies from ‘\VignetteDepends’, possibly of length 0. |
| keywords | a vector of keywords from ‘\VignetteKeyword’, possibly of length 0. |
| engine | the vignetteEngine , such as "utils::Sweave" or "knitr::knitr". |

See Also

[package_dependencies](#) for recursive dependencies.

Examples

```
gridEx <- system.file("doc", "grid.Rnw", package = "grid")
vi <- vignetteInfo(gridEx)
str(vi)
```

| | |
|----------------|--------------------------------|
| write_PACKAGES | <i>Generate PACKAGES Files</i> |
|----------------|--------------------------------|

Description

Generate ‘PACKAGES’, ‘PACKAGES.gz’ and ‘PACKAGES.rds’ files for a repository of source or Mac/Windows binary packages.

Usage

```
write_PACKAGES(dir = ".", fields = NULL,
               type = c("source", "mac.binary", "win.binary"),
               verbose = FALSE, unpacked = FALSE, subdirs = FALSE,
               latestOnly = TRUE, addFiles = FALSE, rds_compress = "xz",
               validate = FALSE)
```

Arguments

| | |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dir | Character vector describing the location of the repository (directory including source or binary packages) to generate the ‘PACKAGES’, ‘PACKAGES.gz’ and ‘PACKAGES.rds’ files from and write them to. |
| fields | a character vector giving the fields to be used in the ‘PACKAGES’, ‘PACKAGES.gz’ and ‘PACKAGES.rds’ files in addition to the default ones, or NULL (default). The default corresponds to the fields needed by available.packages : "Package", "Version", "Priority", "Depends", "Imports", "LinkingTo", "Suggests", "Enhances", "OS_type", "License" and "Archs", and those fields will always be included, plus the file name in field "File" if addFile = TRUE and the path to the subdirectory in field "Path" if subdirectories are used. |
| type | Type of packages: currently source ‘.tar.{gz,bz2,xz}’ archives, and macOS or Windows binary (‘.tgz’ or ‘.zip’, respectively) packages are supported. Defaults to "win.binary" on Windows and to "source" otherwise. |
| verbose | logical. Should packages be listed as they are processed? |
| unpacked | a logical indicating whether the package contents are available in unpacked form or not (default). |
| subdirs | either logical (to indicate if subdirectories should be included, recursively) or a character vector of names of subdirectories to include (which are not recursed). |

| | |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| latestOnly | logical: if multiple versions of a package are available should only the latest version be included? |
| addFiles | logical: should the filenames be included as field 'File' in the 'PACKAGES' file. |
| rds_compress | The type of compression to be used for 'PACKAGES.rds': see saveRDS . The default is the one found to give maximal compression, and is as used on CRAN. |
| validate | a logical indicating whether 'DESCRIPTION' files should be validated, and the corresponding packages skipped in case this finds problems. |

Details

write_PACKAGES scans the named directory for R packages, extracts information from each package's 'DESCRIPTION' file, and writes this information into the 'PACKAGES', 'PACKAGES.gz' and 'PACKAGES.rds' files, where the first two represent the information in DCF format, and the third serializes it via [saveRDS](#).

Including non-latest versions of packages is only useful if they have less constraining version requirements, so for example latestOnly = FALSE could be used for a source repository when 'foo_1.0' depends on 'R >= 2.15.0' but 'foo_0.9' is available which depends on 'R >= 2.11.0'.

Support for repositories with subdirectories and hence for subdirs != FALSE depends on recording a "Path" field in the 'PACKAGES' files.

Support for more general file names (e.g., other types of compression) *via* a "File" field in the 'PACKAGES' files can be used by [download.packages](#). If the file names are not of the standard form, use addFiles = TRUE.

type = "win.binary" uses [unz](#) connections to read all 'DESCRIPTION' files contained in the (zipped) binary packages for Windows in the given directory dir, and builds files 'PACKAGES', 'PACKAGES.gz' and 'PACKAGES.rds' files from this information.

For a remote repository there is a tradeoff between download speed and time spent by [available.packages](#) processing the downloaded file(s). For large repositories it is likely to be beneficial to use rds_compress = "xz".

Value

Invisibly returns the number of packages described in the resulting 'PACKAGES', 'PACKAGES.gz' and 'PACKAGES.rds' files. If 0, no packages were found and no files were written.

Note

Processing '.tar.gz' archives to extract the 'DESCRIPTION' files is quite slow.

This function can be useful on other OSes to prepare a repository to be accessed by Windows machines, so type = "win.binary" should work on all OSes.

Author(s)

Uwe Ligges and R-core.

See Also

See [read.dcf](#) and [write.dcf](#) for reading ‘DESCRIPTION’ files and writing the ‘PACKAGES’ and ‘PACKAGES.gz’ files. See [update_PACKAGES](#) for efficiently updating existing ‘PACKAGES’ and ‘PACKAGES.gz’ files.

Examples

```
## Not run:
write_PACKAGES("c:/myFolder/myRepository") # on Windows
write_PACKAGES("/pub/RWin/bin/windows/contrib/2.9",
               type = "win.binary") # on Linux

## End(Not run)
```

xgettext

*Extract Translatable Messages from R Files in a Package***Description**

For each file in the ‘R’ directory (including system-specific subdirectories) of a *source* package, extract the unique arguments passed to these “message generating” calls;

for `xgettext()`: to [stop](#), [warning](#), [message](#), [packageStartupMessage](#), [gettext](#) and [gettextf](#),
for `xngettext()`: to [ngettext](#).

`xgettext2pot()` calls both `xgettext()` and then `xngettext()`.

Usage

```
xgettext(dir, verbose = FALSE, asCall = TRUE)
```

```
xngettext(dir, verbose = FALSE)
```

```
xgettext2pot(dir, potFile, name = "R", version, bugs)
```

Arguments

| | |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dir</code> | the directory of a source package, i.e., with a ‘./R’ sub directory. |
| <code>verbose</code> | logical: should each file be listed as it is processed? |
| <code>asCall</code> | logical: if TRUE each argument is converted to string and returned whole, otherwise the string literals within each argument are extracted (recursively). See Examples. |
| <code>potFile</code> | name of po template file to be produced. Defaults to ‘R- <i>pkgname</i> .pot’ where <i>pkgname</i> is the basename of ‘dir’. |
| <code>name, version, bugs</code> | as recorded in the template file: version defaults the version number of the currently running R, and bugs to “bugs.r-project.org”. |

Details

Leading and trailing white space (space, tab and linefeed (aka newline, i.e., ‘\n’)) is removed for all the calls extracted by `xgettext()`, see ‘Description’ above, as it is by the internal code that passes strings for translation.

We look to see if the matched functions were called with `domain = NA`. If so, when `asCall` is true, the whole call is omitted. Note that a call might contain a nested call to `gettext` (or `warning`, etc.) whose strings would be visible if `asCall` is false.

`xgettext2pot` calls `xgettext` and then `xngettext`, and writes a PO template file (to `potFile`) for use with the **GNU Gettext** tools. This ensures that the strings for simple translation are unique in the file (as **GNU Gettext** requires), but does not do so for `ngettext` calls (and the rules are not stated in the Gettext manual, but `msgfmt` complains if there is duplication between the sets.).

If applied to the **base** package, this also looks in the ‘.R’ files in ‘[R_HOME](#)/share/R’.

Value

For `xgettext`, a list of objects of class “`xgettext`” (which has a `print` method), one per source file that contains potentially translatable strings.

For `xngettext`, a list of objects of class “`xngettext`”, which are themselves lists of length-2 character vectors.

See Also

[update_pkg_po\(\)](#) which calls `xgettext2pot()`.

Examples

```
## Not run: ## in a source-directory build (not typical!) of R;
## otherwise, download and unpack the R sources, and replace
## R.home() by "<my_path_to_source_R>" :
xgettext(file.path(R.home(), "src", "library", "splines"))

## End(Not run)

## Create source package-like <tmp>/R/foo.R and get text from it:
tmpPkg <- tempdir()
tmpRDir <- file.path(tmpPkg, "R")
dir.create(tmpRDir, showWarnings = FALSE)
fnChar <- paste(sep = "\n",
  "foo <- function(x) {",
  "  if (x < -1) stop('too small')",
  "  # messages unduplicated (not so for ngettext)",
  "  if (x < -.5) stop('too small')",
  "  if (x < 0) {",
  "    warning(",
  "      'sqrt(x) is', sqrt(as.complex(x)),",
  "      ', which may be too small'",
  "    )",
  "  }",
  "  # calls with domain=NA are skipped",
```

```

"  if (x == 0) cat(gettext('x is 0!\n', domain=NA))",
"  # gettext strings may be ignored due to 'outer' domain=NA",
"  if (x > 10) warning('x is ', gettextf('%.2f', x), domain=NA)",
"  # using a custom condition class",
"  if (x == 42)",
"    stop(errorCondition(gettext('needs Deep Thought'), class='myError'))",
"  x",
"}")

writeLines(fnChar, con = file.path(tmpRDir, "foo.R"))

## [[1]] : suppressing (tmpfile) name to make example Rdiff-able
xgettext(tmpPkg, asCall=TRUE)[[1]] # default; shows calls
xgettext(tmpPkg, asCall=FALSE)[[1]] # doesn't ; but then ' %.2f '

unlink(tmpRDir, recursive=TRUE)

```

adist

Approximate String Distances

Description

Compute the approximate string distance between character vectors. The distance is a generalized Levenshtein (edit) distance, giving the minimal possibly weighted number of insertions, deletions and substitutions needed to transform one string into another.

Usage

```
adist(x, y = NULL, costs = NULL, counts = FALSE, fixed = TRUE,  
      partial = !fixed, ignore.case = FALSE, useBytes = FALSE)
```

Arguments

| | |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code> | a character vector. Long vectors are not supported. |
| <code>y</code> | a character vector, or NULL (default) indicating taking <code>x</code> as <code>y</code> . |
| <code>costs</code> | a numeric vector or list with names partially matching ‘insertions’, ‘deletions’ and ‘substitutions’ giving the respective costs for computing the Levenshtein distance, or NULL (default) indicating using unit cost for all three possible transformations. |
| <code>counts</code> | a logical indicating whether to optionally return the transformation counts (numbers of insertions, deletions and substitutions) as the “counts” attribute of the return value. |
| <code>fixed</code> | a logical. If TRUE (default), the <code>x</code> elements are used as string literals. Otherwise, they are taken as regular expressions and <code>partial = TRUE</code> is implied (corresponding to the approximate string distance used by agrep with <code>fixed = FALSE</code>). |
| <code>partial</code> | a logical indicating whether the transformed <code>x</code> elements must exactly match the complete <code>y</code> elements, or only substrings of these. The latter corresponds to the approximate string distance used by agrep (by default). |
| <code>ignore.case</code> | a logical. If TRUE, case is ignored for computing the distances. |
| <code>useBytes</code> | a logical. If TRUE distance computations are done byte-by-byte rather than character-by-character. |

Details

The (generalized) Levenshtein (or edit) distance between two strings s and t is the minimal possibly weighted number of insertions, deletions and substitutions needed to transform s into t (so that the transformation exactly matches t). This distance is computed for `partial = FALSE`, currently using a dynamic programming algorithm (see, e.g., https://en.wikipedia.org/wiki/Levenshtein_distance) with space and time complexity $O(mn)$, where m and n are the lengths of s and t , respectively. Additionally computing the transformation sequence and counts is $O(\max(m, n))$.

The generalized Levenshtein distance can also be used for approximate (fuzzy) string matching, in which case one finds the substring of t with minimal distance to the pattern s (which could be taken as a regular expression, in which case the principle of using the leftmost and longest match applies), see, e.g., https://en.wikipedia.org/wiki/Approximate_string_matching. This distance is computed for `partial = TRUE` using ‘tre’ by Ville Laurikari (<https://github.com/laurikari/tre>) and corresponds to the distance used by [agrep](#). In this case, the given cost values are coerced to integer.

Note that the costs for insertions and deletions can be different, in which case the distance between s and t can be different from the distance between t and s .

Value

A matrix with the approximate string distances of the elements of `x` and `y`, with rows and columns corresponding to `x` and `y`, respectively.

If `counts` is TRUE, the transformation counts are returned as the “counts” attribute of this matrix, as a 3-dimensional array with dimensions corresponding to the elements of `x`, the elements of `y`, and

the type of transformation (insertions, deletions and substitutions), respectively. Additionally, if `partial = FALSE`, the transformation sequences are returned as the `"trafos"` attribute of the return value, as character strings with elements 'M', 'I', 'D' and 'S' indicating a match, insertion, deletion and substitution, respectively. If `partial = TRUE`, the offsets (positions of the first and last element) of the matched substrings are returned as the `"offsets"` attribute of the return value (with both offsets `-1` in case of no match).

See Also

[agrep](#) for approximate string matching (fuzzy matching) using the generalized Levenshtein distance.

Examples

```
## Cf. https://en.wikipedia.org/wiki/Levenshtein_distance
adist("kitten", "sitting")
## To see the transformation counts for the Levenshtein distance:
drop(attr(adist("kitten", "sitting", counts = TRUE), "counts"))
## To see the transformation sequences:
attr(adist(c("kitten", "sitting"), counts = TRUE), "trafos")

## Cf. the examples for agrep:
adist("lasy", "1 lazy 2")
## For a "partial approximate match" (as used for agrep):
adist("lasy", "1 lazy 2", partial = TRUE)
```

alarm

Alert the User

Description

Gives an audible or visual signal to the user.

Usage

```
alarm()
```

Details

`alarm()` works by sending a `"\a"` character to the console. On most platforms this will ring a bell, beep, or give some other signal to the user (unless standard output has been redirected).

It attempts to flush the console (see [flush.console](#)).

Value

No useful value is returned.

Examples

```
alarm()
```

apropos

Find Objects by (Partial) Name

Description

apropos() returns a character vector giving the names of objects in the search list matching (as a regular expression) what.

find() returns where objects of a given name can be found.

Usage

```
apropos(what, where = FALSE, ignore.case = TRUE,  
        dot_internals = FALSE, mode = "any")
```

```
find(what, mode = "any", numeric = FALSE, simple.words = TRUE)
```

Arguments

| | |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| what | character string. For simple.words = FALSE the name of an object; otherwise a regular expression to match object names against. |
| where, numeric | a logical indicating whether positions in the search list should also be returned |
| ignore.case | logical indicating if the search should be case-insensitive, TRUE by default. |
| dot_internals | logical indicating if the search result should show base internal objects, FALSE by default. |
| mode | character; if not "any", only objects whose mode equals mode are searched. |
| simple.words | logical; if TRUE, the what argument is only searched as a whole word. |

Details

If mode != "any" only those objects which are of mode mode are considered.

find is a different user interface for a similar task to apropos. By default (simple.words == TRUE), only whole names are matched. Unlike apropos, matching is always case-sensitive.

Unlike the default behaviour of [ls](#), names which begin with a '.' are included, but base 'internal' objects are included only when dot_internals is true.

Value

For apropos, a character vector sorted by name. For where = TRUE this has names giving the (numerical) positions on the search path.

For find, either a character vector of environment names or (for numeric = TRUE) a numerical vector of positions on the search path with names the names of the corresponding environments.

Author(s)

Originally, Kurt Hornik and Martin Maechler (May 1997).

See Also

[glob2rx](#) to convert wildcard patterns to regular expressions.

[objects](#) for listing objects from one place, [help.search](#) for searching the help system, [search](#) for the search path.

Examples

```
require(stats)

## Not run: apropos("lm")
apropos("GLM")           # several
apropos("GLM", ignore.case = FALSE) # not one
apropos("lq")

cor <- 1:pi
find("cor")              #> ".GlobalEnv"    "package:stats"
find("cor", numeric = TRUE)      # numbers with these names
find("cor", numeric = TRUE, mode = "function") # only the second one
rm(cor)

## Not run: apropos(".", mode = "list") # includes many datasets

# extraction/replacement methods (need a DOUBLE backslash '\\')
apropos("\\[")

# everything % not diff-able
length(apropos("."))

# those starting with 'pr'
apropos("^pr")

# the 1-letter things
apropos("^..$")
# the 1-2-letter things
apropos("^..?$")
# the 2-to-4 letter things
apropos("^.{2,4}$")
# frequencies of 8-and-more letter things
table(nchar(apropos("^.{8,}$")))
```

Description

Determine positions of approximate string matches.

Usage

```
aregexec(pattern, text, max.distance = 0.1, costs = NULL,
          ignore.case = FALSE, fixed = FALSE, useBytes = FALSE)
```

Arguments

| | |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pattern</code> | a non-empty character string or a character string containing a regular expression (for <code>fixed = FALSE</code>) to be matched. Coerced by as.character to a string if possible. |
| <code>text</code> | character vector where matches are sought. Coerced by as.character to a character vector if possible. |
| <code>max.distance</code> | maximum distance allowed for a match. See agrep . |
| <code>costs</code> | cost of transformations. See agrep . |
| <code>ignore.case</code> | a logical. If TRUE, case is ignored for computing the distances. |
| <code>fixed</code> | If TRUE, the pattern is matched literally (as is). Otherwise (default), it is matched as a regular expression. |
| <code>useBytes</code> | a logical. If TRUE comparisons are byte-by-byte rather than character-by-character. |

Details

`aregexec` provides a different interface to approximate string matching than [agrep](#) (along the lines of the interfaces to exact string matching provided by [regexec](#) and [grep](#)).

Note that by default, [agrep](#) performs literal matches, whereas `aregexec` performs regular expression matches.

See [agrep](#) and [adist](#) for more information about approximate string matching and distances.

Comparisons are byte-by-byte if `pattern` or any element of `text` is marked as "bytes".

Value

A list of the same length as `text`, each element of which is either `-1` if there is no match, or a sequence of integers with the starting positions of the match and all substrings corresponding to parenthesized subexpressions of `pattern`, with attribute `"match.length"` an integer vector giving the lengths of the matches (or `-1` for no match).

See Also

[regmatches](#) for extracting the matched substrings.

Examples

```
## Cf. the examples for agrep.
x <- c("1 lazy", "1", "1 LAZY")
aregexec("laysy", x, max.distance = 2)
aregexec("(lay)(sy)", x, max.distance = 2)
aregexec("(lay)(sy)", x, max.distance = 2, ignore.case = TRUE)
m <- aregexec("(lay)(sy)", x, max.distance = 2)
regmatches(x, m)
```

| | |
|----------------|----------------------------------------|
| arrangeWindows | <i>Rearrange Windows on MS Windows</i> |
|----------------|----------------------------------------|

Description

This function allows you to tile or cascade windows, or to minimize or restore them (on Windows, i.e. when (`.Platform$OS.type == "windows"`)). This may include windows not “belonging” to R.

Usage

```
arrangeWindows(action, windows, preserve = TRUE, outer = FALSE)
```

Arguments

| | |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| action | a character string, the action to perform on the windows. The choices are <code>c("vertical", "horizontal", "cascade", "minimize", "restore")</code> with default "vertical"; see the ‘Details’ for the interpretation. Abbreviations may be used. |
| windows | a list of window handles, by default produced by getWindowsHandles() . |
| preserve | If TRUE, when tiling preserve the outer boundary of the collection of windows; otherwise make them as large as will fit. |
| outer | This argument is only used in MDI mode. If TRUE, tile the windows on the system desktop. Otherwise, tile them within the MDI frame. |

Details

The actions are as follows:

"vertical" Tile vertically.

"horizontal" Tile horizontally.

"cascade" Cascade the windows.

"minimize" Minimize all of the windows.

"restore" Restore all of the windows to normal size (not minimized, not maximized).

The tiling and cascading are done by the standard Windows API functions, but unlike those functions, they will apply to all of the windows in the windows list.

By default, windows is set to the result of [getWindowsHandles\(\)](#) (with one exception described below). This will select windows belonging to the current R process. However, if the global environment contains a variable named `.arrangeWindowsDefaults`, it will be used as the argument list instead. See the [getWindowsHandles](#) man page for a discussion of the optional arguments to that function.

When `action = "restore"` is used with windows unspecified, `minimized = TRUE` is added to the argument list of [getWindowsHandles](#) so that minimized windows will be restored.

In MDI mode, by default tiling and cascading will happen within the R GUI frame. However, if `outer = TRUE`, tiling is done on the system desktop. This will generally not give desirable results if any R child windows are included within windows.

Value

This function is called for the side effect of arranging the windows. The list of window handles is returned invisibly.

Note

This is only available on Windows.

Author(s)

Duncan Murdoch

[getWindowsHandles](#)

Examples

```
## Not run: ## Only available on Windows :
arrangeWindows("v")
# This default is useful only in SDI mode: it will tile any Firefox window
# along with the R windows
.arrangeWindowsDefaults <- list(c("R", "all"), pattern = c("", "Firefox"))
arrangeWindows("v")

## End(Not run)
```

askYesNo

Ask a Yes/No Question

Description

askYesNo provides a standard way to ask the user a yes/no question. It provides a way for front-ends to substitute their own dialogs.

Usage

```
askYesNo(msg, default = TRUE,
         prompts = getOption("askYesNo", gettext(c("Yes", "No", "Cancel"))),
         ...)
```

Arguments

| | |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| msg | The prompt message for the user. |
| default | The default response. |
| prompts | Any of: a character vector containing 3 prompts corresponding to return values of TRUE, FALSE, or NA, or a single character value containing the prompts separated by / characters, or a function to call. |
| ... | Additional parameters, ignored by the default function. |

Details

askYesNo will accept case-independent partial matches to the prompts. If no response is given the value of default will be returned; if a non-empty string that doesn't match any of the prompts is entered, an error will be raised.

If a function or single character string naming a function is given for prompts, it will be called as `fn(msg = msg, default = default, prompts = prompts, ...)`. On Windows, the GUI uses the unexported `utils::askYesNoWinDialog` function for this purpose.

If strings (or a string such as "Y/N/C") are given as prompts, the choices will be mapped to lower-case for the non-default choices, and left as-is for the default choice.

Value

TRUE for yes, FALSE for no, and NA for cancel.

See Also

`readline` for more general user input.

Examples

```
if (interactive())
  askYesNo("Do you want to use askYesNo?")
```

| | |
|--------|------------------------------|
| aspell | <i>Spell Check Interface</i> |
|--------|------------------------------|

Description

Spell check given files via Aspell, Hunspell or Ispell.

Usage

```
aspell(files, filter, control = list(), encoding = "unknown",
       program = NULL, dictionaries = character())
```

Arguments

- files a character vector with the names of files to be checked.
- filter an optional filter for processing the files before spell checking, given as either a function (with formals `ifile` and `encoding`), or a character string specifying a built-in filter, or a list with the name of a built-in filter and additional arguments to be passed to it. See **Details** for available filters. If missing or `NULL`, no filtering is performed.
- control a list or character vector of control options for the spell checker.
- encoding the encoding of the files. Recycled as needed.

| | |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| program | a character string giving the name (if on the system path) or full path of the spell check program to be used, or NULL (default). By default, the system path is searched for aspell, hunspell and ispell (in that order), and the first one found is used. |
| dictionaries | a character vector of names or file paths of additional R level dictionaries to use. Elements with no path separator specify R system dictionaries (in subdirectory ‘share/dictionaries’ of the R home directory). The file extension (currently, only ‘.rds’) can be omitted. |

Details

The spell check programs employed must support the so-called Ispell pipe interface activated via command line option ‘-a’. In addition to the programs, suitable dictionaries need to be available. See <http://aspell.net>, <https://hunspell.github.io/> and <https://www.cs.hmc.edu/~geoff/ispell.html>, respectively, for obtaining the Aspell, Hunspell and (International) Ispell programs and dictionaries.

On Windows, Aspell is available via MSYS2. One should use a non-Cygwin version, e.g. package mingw-w64-x86_64-aspell. The version built against the Cygwin runtime (package aspell) requires Unix line endings in files and Unix-style paths, which is incompatible with aspell().

The currently available built-in filters are "Rd" (corresponding to [RdTextFilter](#), with additional argument ignore allowing to give regular expressions for parts of the text to be ignored for spell checking), "Sweave" (corresponding to [SweaveTeXFilter](#)), "R", "pot", "dcf" and "md".

Filter "R" is for R code and extracts the message string constants in calls to [message](#), [warning](#), [stop](#), [packageStartupMessage](#), [gettext](#), [gettextf](#), and [ngettext](#) (the unnamed string constants for the first five, and fmt and msg1/msg2 string constants, respectively, for the latter two).

Filter "pot" is for message string catalog ‘.pot’ files. Both have an argument ignore allowing to give regular expressions for parts of message strings to be ignored for spell checking: e.g., using "[\t]'[^']*'[\t[:punct:]]" ignores all text inside single quotes.

Filter "dcf" is for files in Debian Control File format. The fields to keep can be controlled by argument keep (a character vector with the respective field names). By default, ‘Title’ and ‘Description’ fields are kept.

Filter "md" is for files in [Markdown](#) format (‘.md’ and ‘.Rmd’ files), and needs packages [common-mark](#) and [xml2](#) to be available.

The print method for the objects returned by aspell has an indent argument controlling the indentation of the positions of possibly misspelled words. The default is 2; Emacs users may find it useful to use an indentation of 0 and visit output in grep-mode. It also has a verbose argument: when this is true, suggestions for replacements are shown as well.

It is possible to employ additional R level dictionaries. Currently, these are files with extension ‘.rds’ obtained by serializing character vectors of word lists using [saveRDS](#). If such dictionaries are employed, they are combined into a single word list file which is then used as the spell checker’s personal dictionary (option ‘-p’): hence, the default personal dictionary is not used in this case.

Value

A data frame inheriting from aspell (which has a useful print method) with the information about possibly misspelled words.

Examples

```
## Not run:
## To check all Rd files in a directory, (additionally) skipping the
## \references sections.
files <- Sys.glob("*.Rd")
aspell(files, filter = list("Rd", drop = "\\references"))

## To check all Sweave files
files <- Sys.glob(c("*.Rnw", "*.Snw", "*.rnw", "*.snw"))
aspell(files, filter = "Sweave", control = "-t")

## To check all Texinfo files (Aspell only)
files <- Sys.glob("*.texi")
aspell(files, control = "--mode=texinfo")

## End(Not run)

## List the available R system dictionaries.
Sys.glob(file.path(R.home("share"), "dictionaries", "*.rds"))
```

aspell-utils

Spell Check Utilities

Description

Utilities for spell checking packages via Aspell, Hunspell or Ispell.

Usage

```
aspell_package_Rd_files(dir,
                        drop = c("\\abbr", "\\acronym",
                                "\\author", "\\references"),
                        control = list(), program = NULL,
                        dictionaries = character())
aspell_package_vignettes(dir,
                        control = list(), program = NULL,
                        dictionaries = character())
aspell_package_R_files(dir, ignore = character(), control = list(),
                        program = NULL, dictionaries = character())
```

```
aspell_package_C_files(dir, ignore = character(), control = list(),
                      program = NULL, dictionaries = character())
```

```
aspell_write_personal_dictionary_file(x, out, language = "en",
                                     program = NULL)
```

Arguments

| | |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dir</code> | a character string specifying the path to a package's root directory. |
| <code>drop</code> | a character vector naming additional Rd sections to drop when selecting text via RdTextFilter . |
| <code>control</code> | a list or character vector of control options for the spell checker. |
| <code>program</code> | a character string giving the name (if on the system path) or full path of the spell check program to be used, or NULL (default). By default, the system path is searched for <code>aspell</code> , <code>hunspell</code> and <code>ispell</code> (in that order), and the first one found is used. |
| <code>dictionaries</code> | a character vector of names or file paths of additional R level dictionaries to use. See aspell . |
| <code>ignore</code> | a character vector with regular expressions to be replaced by blanks when filtering the message strings. |
| <code>x</code> | a character vector, or the result of a call to aspell() . |
| <code>out</code> | a character string naming the personal dictionary file to write to. |
| <code>language</code> | a character string indicating a language as used by Aspell. |

Details

Functions `aspell_package_Rd_files`, `aspell_package_vignettes`, `aspell_package_R_files` and `aspell_package_C_files` perform spell checking on the Rd files, vignettes, R files, and C-level messages of the package with root directory `dir`. They determine the respective files, apply the appropriate filters, and run the spell checker.

See [aspell](#) for details on filters.

The C-level message string are obtained from the `'po/PACKAGE.pot'` message catalog file, with `PACKAGE` the basename of `dir`. See the section on 'C-level messages' in 'Writing R Extensions' for more information.

When using Aspell, the vignette checking skips parameters and/or options of commands `\Sexpr`, `\citep`, `\code`, `\pkg`, `\proglang` and `\samp` (in addition to the what the Aspell TeX/L^AT_EX filter skips by default). Further commands can be skipped by adding `--add-tex-command` options to the `control` argument. E.g., to skip both option and parameter of `\mycmd`, add `--add-tex-command='mycmd op'`.

Suitable values for `control`, `program`, `dictionaries`, `drop` and `ignore` can also be specified using a package defaults file which should go as `'defaults.R'` into the `'.aspell'` subdirectory of `dir`, and provides defaults via assignments of suitable named lists, e.g.,

```
vignettes <- list(control = "--add-tex-command='mycmd op'")
```

for vignettes (when using Aspell) and similarly assigning to `Rd_files`, `R_files` and `C_files` for Rd files, R files and C level message defaults.

Maintainers of packages using both English and American spelling will find it convenient to pass control options `--master=en_US` and `--add-extra-dicts=en_GB` to Aspell and control options `-d en_US,en_GB` to Hunspell (provided that the corresponding dictionaries are installed).

Older versions of R had no support for R level dictionaries, and hence provided the function `aspell_write_personal_dictionary_file` to create (spell check) program-specific personal dictionary files from words to be accepted. The new mechanism is to use R level dictionaries, i.e., `.rds` files obtained by serializing character vectors of such words using [saveRDS](#). For such dictionaries specified via the package defaults mechanism, elements with no path separator can be R system dictionaries or dictionaries in the `.aspell` subdirectory.

[aspell](#)

| | |
|---------------------------------|----------------------------------------------------------|
| <code>available.packages</code> | <i>List Available Packages at CRAN-like Repositories</i> |
|---------------------------------|----------------------------------------------------------|

Description

`available.packages` returns a matrix of details corresponding to packages currently available at one or more repositories. The current list of packages is downloaded over the internet (or copied from a local mirror).

Usage

```
available.packages(contriburl = contrib.url(repos, type), method,
                  fields = NULL, type = getOption("pkgType"),
                  filters = NULL, repos = getOption("repos"),
                  ignore_repo_cache = FALSE, max_repo_cache_age,
                  quiet = TRUE, ...)
```

Arguments

| | |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>contriburl</code> | URL(s) of the ‘contrib’ sections of the repositories. Specify this argument only if your repository mirror is incomplete, e.g., because you mirrored only the ‘contrib’ section. |
| <code>method</code> | download method, see download.file . |
| <code>type</code> | character string, indicate which type of packages: see install.packages . If <code>type = "both"</code> this will use the source repository. |
| <code>fields</code> | a character vector giving the fields to extract from the ‘PACKAGES’ file(s) in addition to the default ones, or NULL (default). Unavailable fields result in NA values. |
| <code>filters</code> | a character vector or list or NULL (default). See ‘Details’. |
| <code>repos</code> | character vector, the base URL(s) of the repositories to use. |

ignore_repo_cache
 logical. If true, the repository cache is never used (see ‘Details’).

max_repo_cache_age
 any cached values older than this in seconds will be ignored. See ‘Details’.

quiet
 logical, passed to `download.file()`; change only if you know what you are doing.

...
 allow additional arguments to be passed from callers (which might be arguments to future versions of this function). Currently these are all passed to `download.file()`.

Details

The list of packages is either copied from a local mirror (specified by a ‘file://’ URI) or downloaded. If downloaded and `ignore_repo_cache` is false (the default), the list is cached for the R session in a per-repository file in `tempdir()` with a name like

```
repos_http%3a%2f%2fcran.r-project.org%2fsrc%2fcontrib.rds
```

The cached values are renewed when found to be too old, with the age limit controlled *via* argument `max_repo_cache_age`. This defaults to the current value of the environment variable `R_AVAILABLE_PACKAGES_CACHE_CONTROL_MAX_AGE`, or if unset, to 3600 (one hour).

By default, the return value includes only packages whose version and OS requirements are met by the running version of R, and only gives information on the latest versions of packages.

Argument filters can be used to select which of the packages on the repositories are reported. It is called with its default value (NULL) by functions such as `install.packages`: this value corresponds to `getOption("available_packages_filters")` and to `c("R_version", "OS_type", "subarch", "duplicates")` if that is unset or set to NULL.

The built-in filters are

"R_version" Exclude packages whose R version requirements are not met.

"OS_type" Exclude packages whose OS requirement is incompatible with this version of R: that is exclude Windows-only packages on a Unix-alike platform and *vice versa*.

"subarch" For binary packages, exclude those with compiled code that is not available for the current sub-architecture, e.g. exclude packages only compiled for 32-bit Windows on a 64-bit Windows R.

"duplicates" Only report the latest version where more than one version is available, and only report the first-named repository (in `contriburl`) with the latest version if that is in more than one repository.

"license/FOSS" Include only packages for which installation can proceed solely based on packages which can be verified as Free or Open Source Software (FOSS, e.g., <https://en.wikipedia.org/wiki/FOSS>) employing the available license specifications. Thus both the package and any packages that it depends on to load need to be *known to be* FOSS.

Note that this does depend on the repository supplying license information.

"license/restricts_use" Include only packages for which installation can proceed solely based on packages which are known not to restrict use.

"CRAN" Use CRAN versions in preference to versions from other repositories (even if these have a higher version number). This needs to be applied *before* the default "duplicates" filter, so cannot be used with add = TRUE.

If all the filters are from this set, then they can be specified as a character vector; otherwise filters should be a list with elements which are character strings, user-defined functions or add = TRUE (see below).

User-defined filters are functions which take a single argument, a matrix of the form returned by available.packages, and return a matrix consisting of a subset of the rows of the argument.

The special 'filter' add = TRUE appends the other elements of the filter list to the default filters.

Value

A character matrix with one row per package, row names the package names and column names including "Package", "Version", "Priority", "Depends", "Imports", "LinkingTo", "Suggests", "Enhances", "File" and "Repository". Additional columns can be specified using the fields argument.

Where provided by the repository, fields "OS_type", "License", "License_is_FOSS", "License_restricts_use", "Archs", "MD5sum" and "NeedsCompilation" are reported for use by the filters and package management tools, including [install.packages](#).

See Also

[packageStatus](#), [update.packages](#), [install.packages](#), [download.packages](#), [contrib.url](#).

The 'R Installation and Administration' manual for how to set up a repository.

Examples

```
## Count package licenses
db <- available.packages(repos = findCRANmirror("web"), filters = "duplicates")
table(db[, "License"])

## Use custom filter function to only keep recommended packages
## which do not require compilation
available.packages(repos = findCRANmirror("web"),
  filters = list(
    add = TRUE,
    function (db) db[db[, "Priority"] %in% "recommended" &
      db[, "NeedsCompilation"] == "no", ]
  ))

## Not run:
## Restrict install.packages() (etc) to known-to-be-FOSS packages
options(available_packages_filters =
  c("R_version", "OS_type", "subarch", "duplicates", "license/FOSS"))
## or
options(available_packages_filters = list(add = TRUE, "license/FOSS"))

## Give priority to released versions on CRAN, rather than development
## versions on R-Forge etc.
```

```
options(available_packages_filters =
  c("R_version", "OS_type", "subarch", "CRAN", "duplicates"))

## End(Not run)
```

BATCH

*Batch Execution of R***Description**

Run R non-interactively with input from infile and send output (stdout/stderr) to another file.

Usage

```
R CMD BATCH [options] infile [outfile]
```

Arguments

| | |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| infile | the name of a file with R code to be executed. |
| options | a list of R command line options, e.g., for setting the amount of memory available and controlling the load/save process. If infile starts with a '-', use '--' as the final option. The default options are '--restore --save --no-readline'. (Without '--no-readline' on Windows.) |
| outfile | the name of a file to which to write output. If not given, the name used is that of infile, with a possible '.R' extension stripped, and '.Rout' appended. |

Details

Use R CMD BATCH --help to be reminded of the usage.

By default, the input commands are printed along with the output. To suppress this behavior, add options(echo = FALSE) at the beginning of infile, or use option '--no-echo'.

The infile can have end of line marked by LF or CRLF (but not just CR), and files with an incomplete last line (missing end of line (EOL) mark) are processed correctly.

A final expression 'proc.time()' will be executed after the input script unless the latter calls `q(runLast = FALSE)` or is aborted. This can be suppressed by the option '--no-timing'.

Additional options can be set by the environment variable R_BATCH_OPTIONS: these come after the default options (see the description of the options argument) and before any options given on the command line.

Note

On Unix-alikes only: Unlike Splus BATCH, this does not run the R process in the background. In most shells,

```
R CMD BATCH [options] infile [outfile] &
```

will do so.

bibentry

*Bibliography Entries***Description**

Functionality for representing and manipulating bibliographic information in enhanced BibTeX style.

Usage

```

bibentry(bibtype, textVersion = NULL, header = NULL, footer = NULL,
         key = NULL, ..., other = list(),
         mheader = NULL, mfooter = NULL)

```

```

## S3 method for class 'bibentry'
print(x, style = "text", .bibstyle,
      bibtex = length(x) <= getOption("citation.bibtex.max", 1),
      ...)

```

```

## S3 method for class 'bibentry'
format(x, style = "text", .bibstyle = NULL,
       bibtex = length(x) <= 1,
       citMsg = missing(bibtex),
       sort = FALSE, macros = NULL, ...)

```

```

## S3 method for class 'bibentry'
sort(x, decreasing = FALSE, .bibstyle = NULL, drop = FALSE, ...)

```

```

## S3 method for class 'citation'
print(x, style = "citation", ...)
## S3 method for class 'citation'
format(x, style = "citation", ...)

```

```

## S3 method for class 'bibentry'
toBibtex(object, escape = FALSE, ...)

```

Arguments

| | |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>bibtype</code> | a character string with a BibTeX entry type. See Entry Types for details. |
| <code>textVersion</code> | a character string with a text representation of the reference to optionally be employed for printing. It is recommended to leave this unspecified if <code>format(x, style = "text")</code> works correctly. Only if special LaTeX macros (e.g., math formatting) or special characters (e.g., with accents) are necessary, a <code>textVersion</code> should be provided. |
| <code>header</code> | a character string with optional header text. |
| <code>footer</code> | a character string with optional footer text. |

| | |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| key | a character string giving the citation key for the entry. |
| ... | for <code>bibentry</code> : arguments of the form <code>tag=value</code> giving the fields of the entry, with <code>tag</code> and <code>value</code> the name and value of the field, respectively. Arguments with empty values are dropped. Field names are case-insensitive. See Entry Fields for details. For the <code>print()</code> method, extra arguments to pass to the renderer which typically includes the <code>format()</code> method. For the citation class methods, arguments passed to the next method, i.e., the corresponding <code>bibentry</code> one. For the <code>toBibtex()</code> method, currently not used. |
| other | a list of arguments as in ... (useful in particular for fields named the same as formal arguments of <code>bibentry</code>). |
| mheader | a character string with optional “outer” header text. |
| mfooter | a character string with optional “outer” footer text. |
| x | an object inheriting from class “ <code>bibentry</code> ”. |
| style | an optional character string specifying the print style. If present, must be a unique abbreviation (with case ignored) of the available styles, see Details . |
| decreasing | logical, passed to <code>order</code> indicating the sort direction. |
| .bibstyle | a character string naming a bibliography style, see <code>bibstyle</code> . |
| bibtex | logical indicating if BibTeX code should be given additionally; currently applies only to <code>style = "citation"</code> . The default for the <code>print()</code> method depends on the number of (bib) entries and <code>getOption("citation.bibtex.max")</code> (which itself is 1 by default). For example, to see no BibTeX at all, you can change the default by <code>options(citation.bibtex.max = 0)</code> . |
| citMsg | logical indicating if a “message” should be added (to the footer) about how to get BibTeX code when <code>bibtex</code> is false <i>and</i> <code>style = "citation"</code> . |
| sort | logical indicating if <code>bibentries</code> should be sorted, using <code>bibstyle(.bibstyle)\$sortKeys(x)</code> . |
| macros | a character string or an object with already loaded Rd macros, see Details . |
| drop | logical used as <code>x[, ..., drop=drop]</code> inside the <code>sort()</code> method. |
| object | an object inheriting from class “ <code>bibentry</code> ”. |
| escape | a logical indicating whether non-ASCII characters should be translated to LaTeX escape sequences. |

Details

The `bibentry` objects created by `bibentry` can represent an arbitrary positive number of references. One can use `c()` to combine `bibentry` objects, and hence in particular build a multiple reference object from single reference ones. Alternatively, one can use `bibentry` to directly create a multiple reference object by specifying the arguments as lists of character strings.

The `print` method for `bibentry` objects is based on a corresponding `format` method and provides a choice between seven different styles: plain text (`style "text"`), BibTeX (`"bibtex"`), a mixture of plain text and BibTeX as traditionally used for citations (`"citation"`), HTML (`"html"`), L^AT_EX (`"latex"`), R code (`"R"`), and a simple copy of the `textVersion` elements (`style "textVersion"`).

The "text", "html" and "latex" styles make use of the .bibstyle argument: a style defined by the `bibstyle` function for rendering the bibentry into (intermediate) Rd format. The Rd format uses markup commands documented in the 'Rd format' section of the 'Writing R Extensions' manual, e.g. `\bold`. In addition, one can use the macros argument to provide additional (otherwise unknown, presumably LaTeX-style) Rd macros, either by giving the path to a file with Rd macros to be loaded via `loadRdMacros`, or an object with macros already loaded. Note that the "latex" result may contain commands from the L^AT_EX style file 'Rd.sty' shipped with R; put `\usepackage{Rd}` in the preamble of a LaTeX document to make these available when compiling, e.g. with `texi2pdf`.

When printing bibentry objects in citation style, a header/footer for each item can be displayed as well as a mheader/mfooter for the whole vector of references.

For formatting as R code, a choice between giving a character vector with one `bibentry()` call for each bibentry (as commonly used in 'CITATION' files), or a character string with one collapsed call, obtained by combining the individual calls with `c()` if there is more than one bibentry. This can be controlled by passing the argument `collapse=FALSE` (default) or `TRUE`, respectively, to the `format()` method. (*Printing* in R style always collapses to a single call.)

It is possible to subscript bibentry objects by their keys (which are used for character subscripts if the names are NULL).

There is also a `toBibtex` method for direct conversion to BibTeX.

As of R 4.3.0, there is also a `transform` method which allows to directly use the current fields, see the examples.

Value

bibentry produces an object of class "bibentry".

Entry Types

bibentry creates "bibentry" objects, which are modeled after BibTeX entries. The entry should be a valid BibTeX entry type, e.g.,

Article: An article from a journal or magazine.

Book: A book with an explicit publisher.

InBook: A part of a book, which may be a chapter (or section or whatever) and/or a range of pages.

InCollection: A part of a book having its own title.

InProceedings: An article in a conference proceedings.

Manual: Technical documentation like a software manual.

MastersThesis: A Master's thesis.

Misc: Use this type when nothing else fits.

PhdThesis: A PhD thesis.

Proceedings: The proceedings of a conference.

TechReport: A report published by a school or other institution, usually numbered within a series.

Unpublished: A document having an author and title, but not formally published.

Entry Fields

The ... argument of `bibentry` can be any number of BibTeX fields, including

address: The address of the publisher or other type of institution.

author: The name(s) of the author(s), either as a `person` object, or as a character string which `as.person` correctly coerces to such.

booktitle: Title of a book, part of which is being cited.

chapter: A chapter (or section or whatever) number.

doi: The DOI (https://en.wikipedia.org/wiki/Digital_Object_Identifier) for the reference.

editor: Name(s) of editor(s), same format as author.

institution: The publishing institution of a technical report.

journal: A journal name.

note: Any additional information that can help the reader. The first word should be capitalized.

number: The number of a journal, magazine, technical report, or of a work in a series.

pages: One or more page numbers or range of numbers.

publisher: The publisher's name.

school: The name of the school where a thesis was written.

series: The name of a series or set of books.

title: The work's title.

url: A URL for the reference. (If the URL is an expanded DOI, we recommend to use the 'doi' field with the unexpanded DOI instead.)

volume: The volume of a journal or multi-volume book.

year: The year of publication.

## Combining and subsetting
c(rref, bref)
bref[2]
bref["boot-book"]

## Extracting fields
bref$author
bref[1]$author
bref[1]$author[2]$email

## Field names are case-insensitive
rref$Year
rref$Year <- R.version$year
stopifnot(identical(rref$year, R.version$year))

## Convert to BibTeX
toBibtex(bref)

```

```
## Transform
transform(rref, address = paste0(address, ", Europe"))

## BibTeX reminder message (in case of >= 2 refs):
print(bref, style = "citation")

## Format in R style
## One bibentry() call for each bibentry:
writeLines(paste(format(bref, "R"), collapse = "\n\n"))
## One collapsed call:
writeLines(format(bref, "R", collapse = TRUE))
```

browseEnv

Browse Objects in Environment

Description

The `browseEnv` function opens a browser with list of objects currently in `sys.frame()` environment.

Usage

```
browseEnv(envir = .GlobalEnv, pattern,
          excludepatt = "^last\\.warning",
          html = .Platform$GUI != "AQUA",
          expanded = TRUE, properties = NULL,
          main = NULL, debugMe = FALSE)
```

Arguments

| | |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>envir</code> | an environment the objects of which are to be browsed. |
| <code>pattern</code> | a regular expression for object subselection is passed to the internal <code>ls()</code> call. |
| <code>excludepatt</code> | a regular expression for <i>dropping</i> objects with matching names. |
| <code>html</code> | is used to display the workspace on a HTML page in your favorite browser. The default except when running from R.app on macOS. |
| <code>expanded</code> | whether to show one level of recursion. It can be useful to switch it to FALSE if your workspace is large. This option is ignored if <code>html</code> is set to FALSE. |
| <code>properties</code> | a named list of global properties (of the objects chosen) to be showed in the browser; when NULL (as per default), user, date, and machine information is used. |
| <code>main</code> | a title string to be used in the browser; when NULL (as per default) a title is constructed. |
| <code>debugMe</code> | logical switch; if true, some diagnostic output is produced. |

Details

Very experimental code: displays a static HTML page on all platforms except R.app on macOS.

Only allows one level of recursion into object structures.

It can be generalized. See sources for details. Most probably, this should rather work through using the **tkWidget** package (from <https://www.bioconductor.org>).

[str](#), [ls](#).

Examples

```
if(interactive()) {  
  ## create some interesting objects :  
  ofa <- ordered(4:1)  
  ex1 <- expression(1+ 0:9)  
  ex3 <- expression(u, v, 1+ 0:9)  
  example(factor, echo = FALSE)  
  example(table, echo = FALSE)  
  example(ftable, echo = FALSE)  
  example(lm, echo = FALSE, ask = FALSE)  
  example(str, echo = FALSE)  
  
  ## and browse them:  
  browseEnv()  
  
  ## a (simple) function's environment:  
  af12 <- approxfun(1:2, 1:2, method = "const")  
  browseEnv(envir = environment(af12))  
}
```

browseURL

Load URL into an HTML Browser

Description

Load a given URL into an HTML browser.

Usage

```
browseURL(url, browser = getOption("browser"),  
          encodeIfNeeded = FALSE)
```

Arguments

| | |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| url | a non-empty character string giving the URL to be loaded. Some platforms also accept file paths. |
| browser | <p>a non-empty character string giving the name of the program to be used as the HTML browser. It should be in the PATH, or a full path specified. Alternatively, an R function to be called to invoke the browser.</p> <p>Under Windows NULL is also allowed (and is the default), and implies that the file association mechanism will be used.</p> |
| encodeIfNeeded | Should the URL be encoded by URLencode before passing to the browser? This is not needed (and might be harmful) if the browser program/function itself does encoding, and can be harmful for 'file:/' URLs on some systems and for 'http:/' URLs passed to some CGI applications. Fortunately, most URLs do not need encoding. |

Details

On Unix-alikes: The default browser is set by option "browser", in turn set by the environment variable R_BROWSER which is by default set in file '[R_HOME](#)/etc/Renviron' to a choice made manually or automatically when R was configured. (See [Startup](#) for where to override that default value.) To suppress showing URLs altogether, use the value "false".

On many platforms it is best to set option "browser" to a generic program/script and let that invoke the user's choice of browser. For example, on macOS use open and on many other Unix-alikes use xdg-open.

If browser supports remote control and R knows how to perform it, the URL is opened in any already-running browser or a new one if necessary. This mechanism currently is available for browsers which support the "-remote openURL(...)" interface (which includes Mozilla and Opera), Galeon, KDE konqueror (*via* kfmclient) and the GNOME interface to Mozilla. (Firefox has dropped support, but defaults to using an already-running browser.) Note that the type of browser is determined from its name, so this mechanism will only be used if the browser is installed under its canonical name.

Because "-remote" will use any browser displaying on the X server (whatever machine it is running on), the remote control mechanism is only used if DISPLAY points to the local host. This may not allow displaying more than one URL at a time from a remote host.

It is the caller's responsibility to encode url if necessary (see [URLencode](#)).

To suppress showing URLs altogether, set browser = "false".

The behaviour for arguments url which are not URLs is platform-dependent. Some platforms accept absolute file paths; fewer accept relative file paths.

On Windows: The default browser is set by option "browser", in turn set by the environment variable R_BROWSER if that is set, otherwise to NULL. To suppress showing URLs altogether, use the value "false".

Some browsers have required ':' be replaced by '|' in file paths: others do not accept that. All seem to accept '\' as a path separator even though the RFC1738 standard requires '/'.

To suppress showing URLs altogether, set browser = "false".

URL schemes

Which URL schemes are accepted is platform-specific: expect ‘http://’, ‘https://’ and ‘ftp://’ to work, but ‘mailto:’ may or may not (and if it does may not use the user’s preferred email client). However, modern browsers are unlikely to handle ‘ftp://’.

For the ‘file://’ scheme the format accepted (if any) can depend on both browser and OS.

Examples

```
## Not run:
## for KDE users who want to open files in a new tab
options(browser = "kfmclient newTab")

browseURL("https://www.r-project.org")

## On Windows-only, something like
browseURL("file://d:/R/R-2.5.1/doc/html/index.html",
          browser = "C:/Program Files/Mozilla Firefox/firefox.exe")

## End(Not run)
```

browseVignettes

List Vignettes in an HTML Browser

Description

List available vignettes in an HTML browser with links to PDF, LaTeX/Noweb source, and (tangled) R code (if available).

Usage

```
browseVignettes(package = NULL, lib.loc = NULL, all = TRUE)

## S3 method for class 'browseVignettes'
print(x, ...)
```

Arguments

| | |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------|
| package | a character vector with the names of packages to search through, or NULL in which "all" packages (as defined by argument all) are searched. |
| lib.loc | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. |
| all | logical; if TRUE search all available packages in the library trees specified by lib.loc, and if FALSE, search only attached packages. |
| x | Object of class browseVignettes. |
| ... | Further arguments, ignored by the print method. |

Details

Function `browseVignettes` returns an object of the same class; the `print` method displays it as an HTML page in a browser (using [browseURL](#)).

See Also

[browseURL](#), [vignette](#)

Examples

```
## List vignettes from all *attached* packages
browseVignettes(all = FALSE)

## List vignettes from a specific package
browseVignettes("grid")
```

`bug.report`

Send a Bug Report

Description

Invokes an editor or email program to write a bug report or opens a web page for bug submission. Some standard information on the current version and configuration of **R** are included automatically.

Usage

```
bug.report(subject = "", address,
           file = "R.bug.report", package = NULL, lib.loc = NULL,
           ...)
```

Arguments

| | |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>subject</code> | Subject of the email. |
| <code>address</code> | Recipient's email address, where applicable: for package bug reports sent by email this defaults to the address of the package maintainer (the first if more than one is listed). |
| <code>file</code> | filename to use (if needed) for setting up the email. |
| <code>package</code> | Optional character vector naming a single package which is the subject of the bug report. |
| <code>lib.loc</code> | A character vector describing the location of R library trees in which to search for the package, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. |
| <code>...</code> | additional named arguments such as <code>method</code> and <code>ccaddress</code> to pass to create.post . |

Details

If package is NULL or a base package, this opens the R bugs tracker at <https://bugs.r-project.org/>.

If package is specified, it is assumed that the bug report is about that package, and parts of its 'DESCRIPTION' file are added to the standard information. If the package has a non-empty BugReports field in the 'DESCRIPTION' file specifying the URL of a webpage, that URL will be opened using [browseURL](#), otherwise an email directed to the package maintainer will be generated using [create.post](#). If there is any other form of BugReports field or a Contact field, this is examined as it may provide a preferred email address.

Value

Nothing useful.

When is there a bug?

If R executes an illegal instruction, or dies with an operating system error message that indicates a problem in the program (as opposed to something like "disk full"), then it is certainly a bug.

Taking forever to complete a command can be a bug, but you must make certain that it was really R's fault. Some commands simply take a long time. If the input was such that you KNOW it should have been processed quickly, report a bug. If you don't know whether the command should take a long time, find out by looking in the manual or by asking for assistance.

If a command you are familiar with causes an R error message in a case where its usual definition ought to be reasonable, it is probably a bug. If a command does the wrong thing, that is a bug. But be sure you know for certain what it ought to have done. If you aren't familiar with the command, or don't know for certain how the command is supposed to work, then it might actually be working right. Rather than jumping to conclusions, show the problem to someone who knows for certain.

Finally, a command's intended definition may not be best for statistical analysis. This is a very important sort of problem, but it is also a matter of judgement. Also, it is easy to come to such a conclusion out of ignorance of some of the existing features. It is probably best not to complain about such a problem until you have checked the documentation in the usual ways, feel confident that you understand it, and know for certain that what you want is not available. The mailing list r-devel@r-project.org is a better place for discussions of this sort than the bug list.

If you are not sure what the command is supposed to do after a careful reading of the manual this indicates a bug in the manual. The manual's job is to make everything clear. It is just as important to report documentation bugs as program bugs.

If the online argument list of a function disagrees with the manual, one of them must be wrong, so report the bug.

How to report a bug

When you decide that there is a bug, it is important to report it and to report it in a way which is useful. What is most useful is an exact description of what commands you type, from when you start R until the problem happens. Always include the version of R, machine, and operating system that you are using; type `version` in R to print this. To help us keep track of which bugs have been fixed and which are still open please send a separate report for each bug.

The most important principle in reporting a bug is to report FACTS, not hypotheses or categorizations. It is always easier to report the facts, but people seem to prefer to strain to posit explanations and report them instead. If the explanations are based on guesses about how R is implemented, they will be useless; we will have to try to figure out what the facts must have been to lead to such speculations. Sometimes this is impossible. But in any case, it is unnecessary work for us.

For example, suppose that on a data set which you know to be quite large the command `data.frame(x, y, z, monday, tuesday)` never returns. Do not report that `data.frame()` fails for large data sets. Perhaps it fails when a variable name is a day of the week. If this is so then when we got your report we would try out the `data.frame()` command on a large data set, probably with no day of the week variable name, and not see any problem. There is no way in the world that we could guess that we should try a day of the week variable name.

Or perhaps the command fails because the last command you used was a `[]` method that had a bug causing R's internal data structures to be corrupted and making the `data.frame()` command fail from then on. This is why we need to know what other commands you have typed (or read from your startup file).

It is very useful to try and find simple examples that produce apparently the same bug, and somewhat useful to find simple examples that might be expected to produce the bug but actually do not. If you want to debug the problem and find exactly what caused it, that is wonderful. You should still report the facts as well as any explanations or solutions.

Invoking R with the `--vanilla` option may help in isolating a bug. This ensures that the site profile and saved data files are not read.

A bug report can be generated using the function `bug.report()`. For reports on R this will open the Web page at <https://bugs.r-project.org/>; for a contributed package it will open the package's bug tracker Web page or help you compose an email to the maintainer.

Bug reports on **contributed packages** should not be sent to the R bug tracker: rather make use of the package argument.

Author(s)

This help page is adapted from the Emacs manual and the R FAQ

[help.request](#) which you possibly should try *before* `bug.report`.

[create.post](#), which handles emailing reports.

The R FAQ, also [sessionInfo\(\)](#) from which you may add to the bug report.

capture.output

Send Output to a Character String or File

Description

Evaluates its arguments with the output being returned as a character string or sent to a file. Related to [sink](#) similarly to how [with](#) is related to [attach](#).

Usage

```
capture.output(..., file = NULL, append = FALSE,
               type = c("output", "message"), split = FALSE)
```

Arguments

| | |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>...</code> | Expressions to be evaluated. |
| <code>file</code> | A file name or a connection , or NULL to return the output as a character vector. If the connection is not open, it will be opened initially and closed on exit. |
| <code>append</code> | logical. If file a file name or unopened connection, append or overwrite? |
| <code>type, split</code> | are passed to sink() , see there. |

Details

It works via [sink\(<file connection>\)](#) and hence the R code in dots must *not* interfere with the connection (e.g., by calling [closeAllConnections\(\)](#)).

An attempt is made to write output as far as possible to file if there is an error in evaluating the expressions, but for `file = NULL` all output will be lost.

Messages sent to [stderr\(\)](#) (including those from [message](#), [warning](#) and [stop](#)) are captured by `type = "message"`. Note that this can be “unsafe” and should only be used with care.

Value

A character string (if `file = NULL`), or invisible NULL.

See Also

[sink](#), [textConnection](#)

Examples

```
require(stats)
glmout <- capture.output(summary(glm(case ~ spontaneous+induced,
                                   data = infert, family = binomial()))))

glmout[1:5]
capture.output(1+1, 2+2)
capture.output({1+1; 2+2})

## Not run: ## on Unix-alike with a2ps available
op <- options(useFancyQuotes=FALSE)
pdf <- pipe("a2ps -o - | ps2pdf - tempout.pdf", "w")
capture.output(example(glm), file = pdf)
close(pdf); options(op) ; system("evince tempout.pdf &")

## End(Not run)
```

changedFiles

Detect which Files Have Changed

Description

fileSnapshot takes a snapshot of a selection of files, recording summary information about each. changedFiles compares two snapshots, or compares one snapshot to the current state of the file system. The snapshots need not be the same directory; this could be used to compare two directories.

Usage

```
fileSnapshot(path = ".", file.info = TRUE, timestamp = NULL,
             md5sum = FALSE, digest = NULL, full.names = length(path) > 1,
             ...)

changedFiles(before, after, path = before$path, timestamp = before$timestamp,
             check.file.info = c("size", "isdir", "mode", "mtime"),
             md5sum = before$md5sum, digest = before$digest,
             full.names = before$full.names, ...)

## S3 method for class 'fileSnapshot'
print(x, verbose = FALSE, ...)

## S3 method for class 'changedFiles'
print(x, verbose = FALSE, ...)
```

Arguments

| | |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| path | character vector; the path(s) to record. |
| file.info | logical; whether to record file.info values for each file. |
| timestamp | character string or NULL; the name of a file to write at the time the snapshot is taken. This gives a quick test for modification, but may be unreliable; see the Details . |
| md5sum | logical; whether MD5 summaries of each file should be taken as part of the snapshot. |
| digest | a function or NULL; a function with header function(filename) which will take a vector of filenames and produce a vector of values of the same length, or a matrix with that number of rows. |
| full.names | logical; whether full names (as in list.files) should be recorded. Must be TRUE if length(path) > 1. |
| ... | additional parameters to pass to list.files to control the set of files in the snapshots. |
| before, after | objects produced by fileSnapshot; two snapshots to compare. If after is missing, a new snapshot of the current file system will be produced for comparison, using arguments recorded in before as defaults. |

| | |
|-----------------|---------------------------------------------------------------------------------|
| check.file.info | character vector; which columns from <code>file.info</code> should be compared. |
| x | the object to print. |
| verbose | logical; whether to list all data when printing. |

Details

The `fileSnapshot` function uses `list.files` to obtain a list of files, and depending on the `file.info`, `md5sum`, and `digest` arguments, records information about each file.

The `changedFiles` function compares two snapshots.

If the `timestamp` argument to `fileSnapshot` is length 1, a file with that name is created. If it is length 1 in `changedFiles`, the `file.test` function is used to compare the age of all files common to both before and after to it. This test may be unreliable: it compares the current modification time of the after files to the timestamp; that may not be the same as the modification time when the after snapshot was taken. It may also give incorrect results if the clock on the file system holding the timestamp differs from the one holding the snapshot files.

If the `check.file.info` argument contains a non-empty character vector, the indicated columns from the result of a call to `file.info` will be compared.

If `md5sum` is TRUE, `fileSnapshot` will call the `tools::md5sum` function to record the 32 byte MD5 checksum for each file, and `changedFiles` will compare the values. The `digest` argument allows users to provide their own digest function.

Value

`fileSnapshot` returns an object of class "fileSnapshot". This is a list containing the fields

| | |
|--------------------------------------------------|------------------------------------------------------------------------------------------------------|
| info | a data frame whose rownames are the filenames, and whose columns contain the requested snapshot data |
| path | the normalized path from the call |
| timestamp, file.info, md5sum, digest, full.names | a record of the other arguments from the call |
| args | other arguments passed via ... to <code>list.files</code> . |

`changedFiles` produces an object of class "changedFiles". This is a list containing

| | |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| added, deleted, changed, unchanged | character vectors of filenames from the before and after snapshots, with obvious meanings |
| changes | a logical matrix with a row for each common file, and a column for each comparison test. TRUE indicates a change in that test. |

`print` methods are defined for each of these types. The `print` method for "fileSnapshot" objects displays the arguments used to produce them, while the one for "changedFiles" displays the added, deleted and changed fields if non-empty, and a submatrix of the changes matrix containing all of the TRUE values.

Examples

```
# Create some files in a temporary directory
dir <- tempfile()
dir.create(dir)
writeBin(1L, file.path(dir, "file1"))
writeBin(2L, file.path(dir, "file2"))
dir.create(file.path(dir, "dir"))

# Take a snapshot
snapshot <- fileSnapshot(dir, timestamp = tempfile("timestamp"), md5sum=TRUE)

# Change one of the files.
writeBin(3L:4L, file.path(dir, "file2"))

# Display the detected changes. We may or may not see mtime change...
changedFiles(snapshot)
changedFiles(snapshot)$changes
```

| | |
|-----------|---------------------------------|
| charClass | <i>Character Classification</i> |
|-----------|---------------------------------|

Description

An interface to the (C99) wide character classification functions in use.

Usage

```
charClass(x, class)
```

Arguments

- | | |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------|
| x | Either a UTF-8-encoded length-1 character vector or an integer vector of Uni-code points (or a vector coercible to integer). |
| class | A character string, one of those given in the ‘Details’ section. |

Details

The classification into character classes is platform-dependent. The classes are determined by internal tables on Windows and (optionally but by default) on macOS and AIX.

The character classes are interpreted as follows:

"alnum" Alphabetic or numeric.

"alpha" Alphabetic.

"blank" Space or tab.

"cntrl" Control characters.

"digit" Digits 0–9.

"graph" Graphical characters (printable characters except whitespace).

"lower" Lower-case alphabetic.

"print" Printable characters.

"punct" Punctuation characters. Some platforms treat all non-alphanumeric graphical characters as punctuation.

"space" Whitespace, including tabs, form and line feeds and carriage returns. Some OSes include non-breaking spaces, some exclude them.

"upper" Upper-case alphabetic.

"xdigit" Hexadecimal character, one of 0–9A–fa–f.

Alphabetic characters contain all lower- and upper-case ones and some others (for example, those in ‘title case’).

Whether a character is printable is used to decide whether to escape it when printing – see the help for [print.default](#).

If x is a character string it should either be ASCII or declared as UTF-8 – see [Encoding](#).

charClass was added in R 4.1.0. A less direct way to examine character classes which also worked in earlier versions is to use something like `grepl("[[:print:]]", intToUtf8(x))` – however, the regular-expression code might not use the same classification functions as printing and on macOS used not to.

Value

A logical vector of the length the number of characters or integers in x.

Note

Non-ASCII digits are excluded by the C99 standard from the class "digit": most platforms will have them as alphabetic.

It is an assumption that the system’s wide character classification functions are coded in Unicode points, but this is known to be true for all recent platforms.

The classification may depend on the locale even on one platform.

See Also

Character classes are used in [regular expressions](#).

The OS's man pages for `iswctype` and `wctype`.

Examples

```
x <- c(48:70, 32, 0xa0) # Last is non-breaking space
cl <- c("alnum", "alpha", "blank", "digit", "graph", "punct", "upper", "xdigit")
X <- lapply(cl, function(y) charClass(x,y)); names(X) <- cl
X <- as.data.frame(X); row.names(X) <- sQuote(intToUtf8(x, multiple = TRUE))
X

charClass("ABC123", "alpha")
## Some accented capital Greek characters
(x <- "\u0386\u0388\u0389")
charClass(x, "upper")

## How many printable characters are there? (Around 280,000 in Unicode 13.)
## There are 2^21-1 possible Unicode points (most not yet assigned).
pr <- charClass(1:0xffffffff, "print")
table(pr)
```

choose.dir

Choose a Folder Interactively on MS Windows

Description

Use a Windows shell folder widget to choose a folder interactively.

Usage

```
choose.dir(default = "", caption = "Select folder")
```

Arguments

| | |
|---------|--------------------------------------|
| default | which folder to show initially. |
| caption | the caption on the selection dialog. |

Details

This brings up the Windows shell folder selection widget. With the default `default = ""`, ‘My Computer’ (or similar) is initially selected.

To workaroud a bug, on Vista and later only folders under ‘Computer’ are accessible via the widget.

Value

A length-one character vector, character NA if ‘Cancel’ was selected.

Note

This is only available on Windows.

See Also

[choose.files](#) (on Windows) and [file.choose](#) (on all platforms).

Examples

```
if (interactive() && .Platform$OS.type == "windows")
  choose.dir(getwd(), "Choose a suitable folder")
```

| | |
|--------------|-----------------------------------------------------------|
| choose.files | <i>Choose a List of Files Interactively on MS Windows</i> |
|--------------|-----------------------------------------------------------|

Description

Use a Windows file dialog to choose a list of zero or more files interactively.

Usage

```
choose.files(default = "", caption = "Select files",
             multi = TRUE, filters = Filters,
             index = nrow(Filters))
```

Filters

Arguments

- | | |
|---------|------------------------------------------------|
| default | which filename to show initially |
| caption | the caption on the file selection dialog |
| multi | whether to allow multiple files to be selected |
| filters | a matrix of filename filters (see Details) |
| index | which row of filters to use by default |

Details

Unlike [file.choose](#), `choose.files` will always attempt to return a character vector giving a list of files. If the user cancels the dialog, then zero files are returned, whereas [file.choose](#) would signal an error. `choose.dir` chooses a directory.

Windows file dialog boxes include a list of ‘filters’, which allow the file selection to be limited to files of specific types. The `filters` argument to `choose.files` allows the list of filters to be set. It should be an `n` by 2 character matrix. The first column gives, for each filter, the description the user will see, while the second column gives the mask(s) to select those files. If more than one mask is used, separate them by semicolons, with no spaces. The `index` argument chooses which filter will be used initially.

Filters is a matrix giving the descriptions and masks for the file types that R knows about. Print it to see typical formats for filter specifications. The examples below show how particular filters may be selected.

If you would like to display files in a particular directory, give a fully qualified file mask (e.g., "c:*.*)" in the default argument. If a directory is not given, the dialog will start in the current directory the first time, and remember the last directory used on subsequent invocations.

There is a buffer limit on the total length of the selected filenames: it is large but this function is not intended to select thousands of files, when the limit might be reached.

Value

A character vector giving zero or more file paths.

Note

This is only available on Windows.

See Also

[file.choose](#), [choose.dir](#).

[Sys.glob](#) or [list.files](#) to select multiple files by pattern.

Examples

```
if (interactive() && .Platform$OS.type == "windows")
  choose.files(filters = Filters[c("zip", "All"),])
```

chooseBioCmirror

Select a Bioconductor Mirror

Description

Interact with the user to choose a Bioconductor mirror.

Usage

```
chooseBioCmirror(graphics = getOption("menu.graphics"), ind = NULL,
  local.only = FALSE)
```

Arguments

| | |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| graphics | Logical. If true, use a graphical list: on Windows or the macOS GUI use a list box, and on a Unix-alike use a Tk widget if package tk and an X server are available. Otherwise use a text menu . |
| ind | Optional numeric value giving which entry to select. |
| local.only | Logical, try to get most recent list from the Bioconductor master or use file on local disk only. |

Details

This sets the [option](#) "BioC_mirror": it is used before a call to [setRepositories](#). The out-of-the-box default for that option is NULL, which currently corresponds to the mirror <https://bioconductor.org>.

The 'Bioconductor (World-wide)' 'mirror' is a network of mirrors providing reliable world-wide access; other mirrors may provide faster access on a geographically local scale.

ind chooses a row in '[R_HOME](#)/doc/BioC_mirrors.csv', by number.

Value

None: this function is invoked for its side effect of updating options("BioC_mirror").

See Also

[setRepositories](#), [chooseCRANmirror](#).

| | |
|------------------|-----------------------------|
| chooseCRANmirror | <i>Select a CRAN Mirror</i> |
|------------------|-----------------------------|

Description

Interact with the user to choose a CRAN mirror.

Usage

```
chooseCRANmirror(graphics = getOption("menu.graphics"), ind = NULL,  
                 local.only = FALSE)
```

```
getCRANmirrors(all = FALSE, local.only = FALSE)
```

Arguments

| | |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| graphics | Logical. If true, use a graphical list: on Windows or the macOS GUI use a list box, and on a Unix-alike use a Tk widget if package tcltk and an X server are available. Otherwise use a text menu . |
| ind | Optional numeric value giving which entry to select. |
| all | Logical, get all known mirrors or only the ones flagged as OK. |
| local.only | Logical, try to get most recent list from the CRAN master or use file on local disk only. |

Details

A list of mirrors is stored in file '[R_HOME](#)/doc/CRAN_mirrors.csv', but first an on-line list of current mirrors is consulted, and the file copy used only if the on-line list is inaccessible.

chooseCRANmirror is called by a Windows GUI menu item and by [contrib.url](#) if it finds the initial dummy value of `options("repos")`.

HTTPS mirrors with mirroring over ssh will be offered in preference to other mirrors (which are listed in a sub-menu).

ind chooses a row in the list of current mirrors, by number. It is best used with `local.only = TRUE` and row numbers in '[R_HOME](#)/doc/CRAN_mirrors.csv'.

Value

None for chooseCRANmirror(), this function is invoked for its side effect of updating `options("repos")`.

getCRANmirrors() returns a data frame with mirror information.

See Also

[setRepositories](#), [findCRANmirror](#), [chooseBioCmirror](#), [contrib.url](#).

citation

Citing R and R Packages in Publications

Description

How to cite R and R packages in publications.

Usage

```
citation(package = "base", lib.loc = NULL, auto = NULL)
```

```
readCitationFile(file, meta = NULL)
```

```
citHeader(...)
```

```
citFooter(...)
```

Arguments

package a character string with the name of a single package. An error occurs if more than one package name is given.

lib.loc a character vector with path names of R libraries, or the directory containing the source for package, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.

| | |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>auto</code> | a logical indicating whether the default citation auto-generated from the package ‘DESCRIPTION’ metadata should be used or not, or NULL (default), indicating that a ‘CITATION’ file is used if it exists, or an object of class <code>"packageDescription"</code> with package metadata (see below). |
| <code>file</code> | a file name. |
| <code>meta</code> | a list of package metadata as obtained by <code>packageDescription</code> , or NULL (the default). |
| <code>...</code> | character strings (which will be <code>pasted</code>). |

Details

The R core development team and the very active community of package authors have invested a lot of time and effort in creating R as it is today. Please give credit where credit is due and cite R and R packages when you use them for data analysis.

Execute function `citation()` for information on how to cite the base R system in publications. If the name of a non-base package is given, the function either returns the information contained in the ‘CITATION’ file of the package (using `readCitationFile` with `meta` equal to `packageDescription(package, lib.loc)`) or auto-generates citation information from the ‘DESCRIPTION’ file.

Packages can use an ‘Authors@R’ field in their ‘DESCRIPTION’ to provide (R code giving) a `person` object with a refined, machine-readable description of the package “authors” (in particular specifying their precise roles). Only those with an author role will be included in the auto-generated citation.

If the object returned by `citation()` contains only one reference, the associated print method shows both a text version and a BibTeX entry for it. If a package has more than one reference then only the text versions are shown. This threshold is controlled by `options("citation.bibtex.max")`. The BibTeX versions can also be obtained using function `toBibtex()` (see the examples below).

The ‘CITATION’ file of an R package should be placed in the ‘inst’ subdirectory of the package source. The file is an R source file and may contain arbitrary R commands including conditionals and computations. Function `readCitationFile()` is used by `citation()` to extract the information in ‘CITATION’ files. The file is source()ed by the R parser in a temporary environment and all resulting bibliographic objects (specifically, inheriting from `"bibentry"`) are collected. These are typically produced by one or more `bibentry()` calls, optionally preceded by a `citHeader()` and followed by a `citFooter()` call. One can include an auto-generated package citation in the ‘CITATION’ file via `citation(auto = meta)`.

`readCitationFile` makes use of the Encoding element (if any) of `meta` to determine the encoding of the file.

Value

An object of class `"citation"`, inheriting from class `"bibentry"`; see there, notably for the `print` and `format` methods.

`citHeader` and `citFooter` return an empty `"bibentry"` storing “outer” header/footer text for the package citation.

See Also[bibentry](#)**Examples**

```
## the basic R reference
citation()

## extract the BibTeX entry from the return value
x <- citation()
toBibtex(x)

## references for a package
citation("lattice")
citation("lattice", auto = TRUE) # request the Manual-type reference
citation("foreign")

## a CITATION file with more than one bibentry:
file.show(system.file("CITATION", package="mgcv"))
cm <- citation("mgcv")
cm # header, text references, plus "reminder" about getting BibTeX
print(cm, bibtex = TRUE) # each showing its bibtex code

## a CITATION file including citation(auto = meta)
file.show(system.file("CITATION", package="nlme"))
citation("nlme")
```

cite

Cite a Bibliography Entry

Description

Cite a [bibentry](#) object in text. The `cite()` function uses the `cite()` function from the default [bibstyle](#) if present, or `citeNatbib()` if not. `citeNatbib()` uses a style similar to that used by the LaTeX package **natbib**.

Usage

```
cite(keys, bib, ...)
citeNatbib(keys, bib, textual = FALSE, before = NULL, after = NULL,
  mode = c("authoryear", "numbers", "super"),
  abbreviate = TRUE, longnamesfirst = TRUE,
  bibpunct = c("(", ")", ";", "a", "", ","), previous)
```

Arguments

| | |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| keys | A character vector of keys of entries to cite. May contain multiple keys in a single entry, separated by commas. |
| bib | A " bibentry " object containing the list of documents in which to find the keys. |
| ... | Additional arguments to pass to the <code>cite()</code> function for the default style. |
| textual | Produce a "textual" style of citation, i.e. what <code>\citet</code> would produce in LaTeX. |
| before | Optional text to display before the citation. |
| after | Optional text to display after the citation. |
| mode | The "mode" of citation. |
| abbreviate | Whether to abbreviate long author lists. |
| longnamesfirst | If <code>abbreviate == TRUE</code> , whether to leave the first citation long. |
| bibpunct | A vector of punctuation to use in the citation, as used in natbib . See the Details section. |
| previous | A list of keys that have been previously cited, to be used when <code>abbreviate == TRUE</code> and <code>longnamesfirst == TRUE</code> |

Details

Argument names are chosen based on the documentation for the LaTeX **natbib** package. See that documentation for the interpretation of the `bibpunct` entries.

The entries in `bibpunct` are as follows:

1. The left delimiter.
2. The right delimiter.
3. The separator between references within a citation.
4. An indicator of the "mode": "n" for numbers, "s" for superscripts, anything else for author-year.
5. Punctuation to go between the author and year.
6. Punctuation to go between years when authorship is suppressed.

Note that if `mode` is specified, it overrides the mode specification in `bibpunct[4]`. Partial matching is used for `mode`.

The defaults for `citeNatbib` have been chosen to match the JSS style, and by default these are used in `cite`. See [bibstyle](#) for how to set a different default style.

Value

A single element character string is returned, containing the citation.

)

## Combine and cite
refs <- c(rref, bref)
cite("R, boot-package", refs)

## Cite numerically
savestyle <- tools::getBibstyle()
tools::bibstyle("JSSnumbered", .init = TRUE,
  fmtPrefix = function(paper) paste0("[", paper$.index, "]"),
  cite = function(key, bib, ...)
```

```

        citeNatbib(key, bib, mode = "numbers",
                    bibpunct = c("[", "]", ";", "n", "", ","), ...)
    )
    cite("R, boot-package", refs, textual = TRUE)
    refs

## restore the old style
tools::bibstyle(savestyle, .default = TRUE)

```

citEntry

Bibliography Entries (Older Interface)

Description

Old interface providing functionality for specifying bibliographic information in enhanced BibTeX style. Since R 2.14.0 this has been superseded by [bibentry](#).

Usage

```
citEntry(entry, textVersion = NULL, header = NULL, footer = NULL, ...)
```

Arguments

| | |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| entry | a character string with a BibTeX entry type. See section Entry Types in bibentry for details. |
| textVersion | a character string with a text representation of the reference to optionally be employed for printing. |
| header | a character string with optional header text. |
| footer | a character string with optional footer text. |
| ... | for citEntry, arguments of the form <i>tag=value</i> giving the fields of the entry, with <i>tag</i> and <i>value</i> the name and value of the field, respectively. See section Entry Fields in bibentry for details. |

Value

citEntry produces an object of class "bibentry".

See Also

[citation](#) for more information about citing R and R packages and 'CITATION' files; [bibentry](#) for the newer functionality for representing and manipulating bibliographic information.

clipboard

*Read/Write to/from the Clipboard in MS Windows***Description**

Transfer text between a character vector and the Windows clipboard in MS Windows (only).

Usage

```
getClipboardFormats(numeric = FALSE)
readClipboard(format = 13, raw = FALSE)
writeClipboard(str, format = 13)
```

Arguments

| | |
|---------|------------------------------------------------------------------------------------|
| numeric | logical: should the result be in human-readable form (the default) or raw numbers? |
| format | an integer giving the desired format. |
| raw | should the value be returned as a raw vector rather than as a character vector? |
| str | a character vector or a raw vector. |

Details

The Windows clipboard offers data in a number of formats: see e.g. <https://docs.microsoft.com/en-gb/windows/desktop/dataxchg/clipboard-formats>.

The standard formats include

| | | |
|-----------------|----|--------------------------------------|
| CF_TEXT | 1 | Text in the machine's locale |
| CF_BITMAP | 2 | |
| CF_METAFILEPICT | 3 | Metafile picture |
| CF_SYLK | 4 | Symbolic link |
| CF_DIF | 5 | Data Interchange Format |
| CF_TIFF | 6 | Tagged-Image File Format |
| CF_OEMTEXT | 7 | Text in the OEM codepage |
| CF_DIB | 8 | Device-Independent Bitmap |
| CF_PALETTE | 9 | |
| CF_PENDATA | 10 | |
| CF_RIFF | 11 | Audio data |
| CF_WAVE | 12 | Audio data |
| CF_UNICODETEXT | 13 | Text in Unicode (UCS-2) |
| CF_ENHMETAFILE | 14 | Enhanced metafile |
| CF_HDROP | 15 | Drag-and-drop data |
| CF_LOCALE | 16 | Locale for the text on the clipboard |
| CF_MAX | 17 | Shell-oriented formats |

Applications normally make data available in one or more of these and possibly additional private formats. Use `raw = TRUE` to read binary formats, `raw = FALSE` (the default) for text formats. The current codepage is used to convert text to Unicode text, and information on that is contained in the `CF_LOCALE` format. (Take care if you are running R in a different locale from Windows. It is recommended to read as Unicode text, so that Windows does the conversion based on `CF_LOCALE`, if available.)

The `writeClipboard` function will write a character vector as text or Unicode text with standard CRLF line terminators. It will copy a raw vector directly to the clipboard without any changes. It is recommended to use Unicode text (the default) instead of text to avoid interoperability problems. (Note that R 4.2 and newer on recent systems uses UTF-8 as the native encoding but the machine's locale uses a different encoding.)

Value

For `getClipboardFormats`, a character or integer vector of available formats, in numeric order. If non human-readable character representation is known, the number is returned.

For `readClipboard`, a character vector by default, a raw vector if `raw` is `TRUE`, or `NULL`, if the format is unavailable.

For `writeClipboard` an invisible logical indicating success or failure.

Note

This is only available on Windows.

See Also

[file](#) which can be used to set up a connection to a clipboard.

close.socket

Close a Socket

Description

Closes the socket and frees the space in the file descriptor table. The port may not be freed immediately.

Usage

```
close.socket(socket, ...)
```

Arguments

| | |
|--------|----------------------------------------------------|
| socket | a socket object |
| ... | further arguments passed to or from other methods. |

Value

logical indicating success or failure

Author(s)

Thomas Lumley

See Also[make.socket](#), [read.socket](#)

Compiling in support for sockets was optional prior to R 3.3.0: see [capabilities\("sockets"\)](#) to see if it is available.

combn

*Generate All Combinations of n Elements, Taken m at a Time***Description**

Generate all combinations of the elements of x taken m at a time. If x is a positive integer, returns all combinations of the elements of `seq(x)` taken m at a time. If argument `FUN` is not `NULL`, applies a function given by the argument to each point. If `simplify` is `FALSE`, returns a list; otherwise returns an [array](#), typically a [matrix](#). ... are passed unchanged to the `FUN` function, if specified.

Usage

```
combn(x, m, FUN = NULL, simplify = TRUE, ...)
```

Arguments

| | |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code> | vector source for combinations, or integer n for <code>x <- seq_len(n)</code> . |
| <code>m</code> | number of elements to choose. |
| <code>FUN</code> | function to be applied to each combination; default <code>NULL</code> means the identity, i.e., to return the combination (vector of length m). |
| <code>simplify</code> | logical indicating if the result should be simplified to an array (typically a matrix); if <code>FALSE</code> , the function returns a list . Note that when <code>simplify = TRUE</code> as by default, the dimension of the result is simply determined from <code>FUN(1st combination)</code> (for efficiency reasons). This will badly fail if <code>FUN(u)</code> is not of constant length. |
| <code>...</code> | optionally, further arguments to <code>FUN</code> . |

Details

Factors x are accepted.

Value

A [list](#) or [array](#), see the `simplify` argument above. In the latter case, the identity `dim(combn(n, m)) == c(m, choose(n, m))` holds.

Author(s)

Scott Chasalow wrote the original in 1994 for S; R package **combinat** and documentation by Vince Carey <stvjc@channing.harvard.edu>; small changes by the R core team, notably to return an array in all cases of simplify = TRUE, e.g., for combn(5,5).

References

Nijenhuis, A. and Wilf, H.S. (1978) *Combinatorial Algorithms for Computers and Calculators*; Academic Press, NY.

See Also

[choose](#) for fast computation of the *number* of combinations. [expand.grid](#) for creating a data frame from all combinations of factors or vectors.

Examples

```
combn(letters[1:4], 2)
(m <- combn(10, 5, min)) # minimum value in each combination
mm <- combn(15, 6, function(x) matrix(x, 2, 3))
stopifnot(round(choose(10, 5)) == length(m), is.array(m), # 1-dimensional
           c(2,3, round(choose(15, 6))) == dim(mm))

## Different way of encoding points:
combn(c(1,1,1,1,2,2,2,3,3,4), 3, tabulate, nbins = 4)

## Compute support points and (scaled) probabilities for a
## Multivariate-Hypergeometric(n = 3, N = c(4,3,2,1)) p.f.:
# table.mat(t(combn(c(1,1,1,1,2,2,2,3,3,4), 3, tabulate, nbins = 4)))

## Assuring the identity
for(n in 1:7)
  for(m in 0:n) stopifnot(is.array(cc <- combn(n, m)),
                        dim(cc) == c(m, choose(n, m)),
                        identical(cc, combn(n, m, identity)) || m == 1)
```

compareVersion

Compare Two Package Version Numbers

Description

Compare two package version numbers to see which is later.

Usage

```
compareVersion(a, b)
```

Arguments

a, b Character strings representing package version numbers.

Details

R package version numbers are of the form x.y-z for integers x, y and z, with components after x optionally missing (in which case the version number is older than those with the components present).

Value

0 if the numbers are equal, -1 if b is later and 1 if a is later (analogous to the C function strcmp).

See Also

[package_version](#), [library](#), [packageStatus](#).

Examples

```
compareVersion("1.0", "1.0-1")
compareVersion("7.2-0", "7.1-12")
```

 COMPILE

Compile Files for Use with R on Unix-alikes

Description

Compile given source files so that they can subsequently be collected into a shared object using R CMD SHLIB or an executable program using R CMD LINK. Not available on Windows.

Usage

```
R CMD COMPILE [options] srcfiles
```

Arguments

| | |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| srcfiles | A list of the names of source files to be compiled. Currently, C, C++, Objective C, Objective C++ and Fortran are supported; the corresponding files should have the extensions <code>‘.c’</code> , <code>‘.cc’</code> (or <code>‘.cpp’</code>), <code>‘.m’</code> , <code>‘.mm’</code> (or <code>‘.M’</code>), <code>‘.f’</code> and <code>‘.f90’</code> or <code>‘.f95’</code> , respectively. |
| options | A list of compile-relevant settings, or for obtaining information about usage and version of the utility. |

Details

R CMD SHLIB can both compile and link files into a shared object: since it knows what run-time libraries are needed when passed C++, Fortran and Objective C(++) sources, passing source files to R CMD SHLIB is more reliable.

Objective C and Objective C++ support is optional and will work only if the corresponding compilers were available at R configure time: their main usage is on macOS.

Compilation arranges to include the paths to the R public C/C++ headers.

As this compiles code suitable for incorporation into a shared object, it generates PIC code: that might occasionally be undesirable for the main code of an executable program.

This is a make-based facility, so will not compile a source file if a newer corresponding ‘.o’ file is present.

Note

Some binary distributions of R have COMPILE in a separate bundle, e.g. an R-devel RPM.

This is not available on Windows.

See Also

contrib.url

Find Appropriate Paths in CRAN-like Repositories

Description

contrib.url adds the appropriate type-specific path within a repository to each URL in repos.

Usage

```
contrib.url(repos, type = getOption("pkgType"))
```

Arguments

| | |
|-------|---------------------------------------------------------------------------------------------|
| repos | character vector, the base URL(s) of the repositories to use. |
| type | character string, indicating which type of packages: see install.packages . |

Details

If type = "both" this will use the source repository.

Value

A character vector of the same length as repos.

See Also

[setRepositories](#) to set [options\("repos"\)](#), the most common value used for argument `repos`.

| <code>count.fields</code> | <i>Count the Number of Fields per Line</i> |
|---------------------------|--------------------------------------------|

Description

`count.fields` counts the number of fields, as separated by `sep`, in each of the lines of `file` read.

Usage

```
count.fields(file, sep = "", quote = "\"'", skip = 0,  
             blank.lines.skip = TRUE, comment.char = "#")
```

Arguments

- | | |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>file</code> | a character string naming an ASCII data file, or a connection , which will be opened if necessary, and if so closed at the end of the function call. |
| <code>sep</code> | the field separator character. Values on each line of the file are separated by this character. By default, arbitrary amounts of whitespace can separate fields. |
| <code>quote</code> | the set of quoting characters |
| <code>skip</code> | the number of lines of the data file to skip before beginning to read data. |
| <code>blank.lines.skip</code> | logical: if TRUE blank lines in the input are ignored. |
| <code>comment.char</code> | character: a character vector of length one containing a single character or an empty string. |

Details

This used to be used by [read.table](#) and can still be useful in discovering problems in reading a file by that function.

For the handling of comments, see [scan](#).

Consistent with [scan](#), `count.fields` allows quoted strings to contain newline characters. In such a case the starting line will have the field count recorded as NA, and the ending line will include the count of all fields from the beginning of the record.

Value

A vector with the numbers of fields found.

See Also

[read.table](#)

Examples

```
fil <- tempfile()
cat("NAME", "1:John", "2:Paul", file = fil, sep = "\n")
count.fields(fil, sep = ":")
unlink(fil)
```

| | |
|-------------|-------------------------------------------------------------|
| create.post | <i>Ancillary Function for Preparing Emails and Postings</i> |
|-------------|-------------------------------------------------------------|

Description

An ancillary function used by [bug.report](#) and [help.request](#) to prepare emails for submission to package maintainers or to R mailing lists.

Usage

```
create.post(instructions = character(), description = "post",
            subject = "",
            method = getOption("mailer"),
            address = "the relevant mailing list",
            ccaddress = getOption("ccaddress", ""),
            filename = "R.post", info = character())
```

Arguments

| | |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| instructions | Character vector of instructions to put at the top of the template email. |
| description | Character string: a description to be incorporated into messages. |
| subject | Subject of the email. Optional except for the "mailx" method. |
| method | Submission method, one of "none", "mailto", "gnudoit", "ess" or (Unix only) "mailx". See 'Details'. |
| address | Recipient's email address, where applicable: for package bug reports sent by email this defaults to the address of the package maintainer (the first if more than one is listed). |
| ccaddress | Optional email address for copies with the "mailx" and "mailto" methods. Use ccaddress = "" for no copy. |
| filename | Filename to use for setting up the email (or storing it when method is "none" or sending mail fails). |
| info | character vector of information to include in the template email below the 'please do not edit the information below' line. |

Details

What this does depends on the method. The function first creates a template email body.

`none` A file editor (see [file.edit](#)) is opened with instructions and the template email. When this returns, the completed email is in file `file` ready to be read/pasted into an email program.

`mailto` This opens the default email program with a template email (including address, Cc: address and subject) for you to edit and send.

This works where default mailers are set up (usual on macOS and Windows, and where `xdg-open` is available and configured on other Unix-alikes: if that fails it tries the browser set by `R_BROWSER`).

This is the ‘factory-fresh’ default method.

`mailx` (Unix-alikes only.) A file editor (see [file.edit](#)) is opened with instructions and the template email. When this returns, it is mailed using a Unix command line mail utility such as `mailx`, to the address (and optionally, the Cc: address) given.

`gnudoit` An (X)emacs mail buffer is opened for the email to be edited and sent: this requires the `gnudoit` program to be available. Currently subject is ignored.

`ess` The body of the template email is sent to `stdout`.

Value

Invisible `NULL`.

See Also

[bug.report](#), [help.request](#).

data

Data Sets

Description

Loads specified data sets, or list the available data sets.

Usage

```
data(..., list = character(), package = NULL, lib.loc = NULL,
      verbose = getOption("verbose"), envir = .GlobalEnv,
      overwrite = TRUE)
```

Arguments

| | |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>...</code> | literal character strings or names. |
| <code>list</code> | a character vector. |
| <code>package</code> | a character vector giving the package(s) to look in for data sets, or <code>NULL</code> . By default, all packages in the search path are used, then the ‘data’ subdirectory (if present) of the current working directory. |

| | |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <code>lib.loc</code> | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. |
| <code>verbose</code> | a logical. If TRUE, additional diagnostics are printed. |
| <code>envir</code> | the environment where the data should be loaded. |
| <code>overwrite</code> | logical: should existing objects of the same name in <code>envir</code> be replaced? |

Details

Currently, four formats of data files are supported:

1. files ending `‘.R’` or `‘.r’` are [source\(\)](#)d in, with the R working directory changed temporarily to the directory containing the respective file. (data ensures that the [utils](#) package is attached, in case it had been run *via* `utils::data`.)
2. files ending `‘.RData’` or `‘.rda’` are [load\(\)](#)ed.
3. files ending `‘.tab’`, `‘.txt’` or `‘.TXT’` are read using [read.table\(..., header = TRUE, as.is=FALSE\)](#), and hence result in a data frame.
4. files ending `‘.csv’` or `‘.CSV’` are read using [read.table\(..., header = TRUE, sep = “;”, as.is=FALSE\)](#), and also result in a data frame.

If more than one matching file name is found, the first on this list is used. (Files with extensions `‘.txt’`, `‘.tab’` or `‘.csv’` can be compressed, with or without further extension `‘.gz’`, `‘.bz2’` or `‘.xz’`.)

The data sets to be loaded can be specified as a set of character strings or names, or as the character vector `list`, or as both.

For each given data set, the first two types (`‘.R’` or `‘.r’`, and `‘.RData’` or `‘.rda’` files) can create several variables in the load environment, which might all be named differently from the data set. The third and fourth types will always result in the creation of a single variable with the same name (without extension) as the data set.

If no data sets are specified, `data` lists the available data sets. For each package, it looks for a data index in the `‘Meta’` subdirectory or, if this is not found, scans the `‘data’` subdirectory for data files using [list_files_with_type](#). The information about available data sets is returned in an object of class `“packageIQR”`. The structure of this class is experimental. Where the datasets have a different name from the argument that should be used to retrieve them the index will have an entry like `beaver1` (`beavers`) which tells us that dataset `beaver1` can be retrieved by the call `data(beavers)`.

If `lib.loc` and `package` are both NULL (the default), the data sets are searched for in all the currently loaded packages then in the `‘data’` directory (if any) of the current working directory.

If `lib.loc` = NULL but `package` is specified as a character vector, the specified package(s) are searched for first amongst loaded packages and then in the default libraries (see [.libPaths](#)).

If `lib.loc` is specified (and not NULL), packages are searched for in the specified libraries, even if they are already loaded from another library.

To just look in the `‘data’` directory of the current working directory, set `package = character(0)` (and `lib.loc` = NULL, the default).

Value

A character vector of all data sets specified (whether found or not), or information about all available data sets in an object of class "packageIQR" if none were specified.

Good practice

There is no requirement for `data(foo)` to create an object named `foo` (nor to create one object), although it much reduces confusion if this convention is followed (and it is enforced if datasets are lazy-loaded).

`data()` was originally intended to allow users to load datasets from packages for use in their examples, and as such it loaded the datasets into the workspace `.GlobalEnv`. This avoided having large datasets in memory when not in use: that need has been almost entirely superseded by lazy-loading of datasets.

The ability to specify a dataset by name (without quotes) is a convenience: in programming the datasets should be specified by character strings (with quotes).

Use of `data` within a function without an `envir` argument has the almost always undesirable side-effect of putting an object in the user's workspace (and indeed, of replacing any object of that name already there). It would almost always be better to put the object in the current evaluation environment by `data(..., envir = environment())`. However, two alternatives are usually preferable, both described in the 'Writing R Extensions' manual.

- For sets of data, set up a package to use lazy-loading of data.
- For objects which are system data, for example lookup tables used in calculations within the function, use a file 'R/sysdata.rda' in the package sources or create the objects by R code at package installation time.

A sometimes important distinction is that the second approach places objects in the namespace but the first does not. So if it is important that the function sees `mytable` as an object from the package, it is system data and the second approach should be used. In the unusual case that a package uses a lazy-loaded dataset as a default argument to a function, that needs to be specified by `::`, e.g., `survival::survexp.us`.

Warning

This function creates objects in the `envir` environment (by default the user's workspace) replacing any which already existed. `data("foo")` can silently create objects other than `foo`: there have been instances in published packages where it created/replaced `.Random.seed` and hence change the seed for the session.

Note

One can take advantage of the search order and the fact that a '.R' file will change directory. If raw data are stored in 'mydata.txt' then one can set up 'mydata.R' to read 'mydata.txt' and pre-process it, e.g., using `transform()`. For instance one can convert numeric vectors to factors with the appropriate labels. Thus, the '.R' file can effectively contain a metadata specification for the plaintext formats.

See Also

[help](#) for obtaining documentation on data sets, [save](#) for *creating* the second (`.rda`) kind of data, typically the most efficient one.

The ‘Writing R Extensions’ manual for considerations in preparing the ‘data’ directory of a package.

Examples

```
require(utils)
data() # list all available data sets
try(data(package = "rpart"), silent = TRUE) # list the data sets in the rpart package
data(USArrests, "VADeaths") # load the data sets 'USArrests' and 'VADeaths'
## Not run: ## Alternatively
ds <- c("USArrests", "VADeaths"); data(list = ds)
## End(Not run)
help(USArrests) # give information on data set 'USArrests'
```

| | |
|-----------|------------------------------------------------|
| dataentry | <i>Spreadsheet Interface for Entering Data</i> |
|-----------|------------------------------------------------|

Description

A spreadsheet-like editor for entering or editing data.

Usage

```
data.entry(..., Modes = NULL, Names = NULL)
dataentry(data, modes)
de(..., Modes = list(), Names = NULL)
```

Arguments

| | |
|-------|------------------------------------------------------------------------------------------------------------------|
| ... | A list of variables: currently these should be numeric or character vectors or list containing such vectors. |
| Modes | The modes to be used for the variables. |
| Names | The names to be used for the variables. |
| data | A list of numeric and/or character vectors. |
| modes | A list of length up to that of data giving the modes of (some of) the variables. <code>list()</code> is allowed. |

Details

The data entry editor is only available on some platforms and GUIs. Where available it provides a means to visually edit a matrix or a collection of variables (including a data frame) as described in the Notes section.

`data.entry` has side effects, any changes made in the spreadsheet are reflected in the variables. Function `de` and the internal functions `de.ncols`, `de.setup` and `de.restore` are designed to help achieve these side effects. If the user passes in a matrix, `X` say, then the matrix is broken into columns before `dataentry` is called. Then on return the columns are collected and glued back together and the result assigned to the variable `X`. If you don't want this behaviour use `dataentry` directly.

The primitive function is `dataentry`. It takes a list of vectors of possibly different lengths and modes (the second argument) and opens a spreadsheet with these variables being the columns. The columns of the data entry window are returned as vectors in a list when the spreadsheet is closed.

`de.ncols` counts the number of columns which are supplied as arguments to `data.entry`. It attempts to count columns in lists, matrices and vectors. `de.setup` sets things up so that on return the columns can be regrouped and reassigned to the correct name. This is handled by `de.restore`.

Value

`de` and `dataentry` return the edited value of their arguments. `data.entry` invisibly returns a vector of variable names but its main value is its side effect of assigning new version of those variables in the user's workspace.

Resources

The data entry window responds to X resources of class `R_dataentry`. Resources foreground, background and geometry are utilized.

Note

The details of interface to the data grid may differ by platform and GUI. The following description applies to the X11-based implementation under Unix.

You can navigate around the grid using the cursor keys or by clicking with the (left) mouse button on any cell. The active cell is highlighted by thickening the surrounding rectangle. Moving to the right or down will scroll the grid as needed: there is no constraint to the rows or columns currently in use.

There are alternative ways to navigate using the keys. Return and (keypad) Enter and LineFeed all move down. Tab moves right and Shift-Tab move left. Home moves to the top left.

PageDown or Control-F moves down a page, and PageUp or Control-B up by a page. End will show the last used column and the last few rows used (in any column).

Using any other key starts an editing process on the currently selected cell: moving away from that cell enters the edited value whereas Esc cancels the edit and restores the previous value. When the editing process starts the cell is cleared. In numerical columns (the default) only letters making up a valid number (including `-`, `eE`) are accepted, and entering an invalid edited value (such as blank) enters NA in that cell. The last entered value can be deleted using the BackSpace or Del(ete) key. Only a limited number of characters (currently 29) can be entered in a cell, and if necessary only

the start or end of the string will be displayed, with the omissions indicated by > or <. (The start is shown except when editing.)

Entering a value in a cell further down a column than the last used cell extends the variable and fills the gap (if any) by NAs (not shown on screen).

The column names can only be selected by clicking in them. This gives a popup menu to select the column type (currently Real (numeric) or Character) or to change the name. Changing the type converts the current contents of the column (and converting from Character to Real may generate NAs.) If changing the name is selected the header cell becomes editable (and is cleared). As with all cells, the value is entered by moving away from the cell by clicking elsewhere or by any of the keys for moving down (only).

New columns are created by entering values in them (and not by just assigning a new name). The mode of the column is auto-detected from the first value entered: if this is a valid number it gives a numeric column. Unused columns are ignored, so adding data in var5 to a three-column grid adds one extra variable, not two.

The Copy button copies the currently selected cell: paste copies the last copied value to the current cell, and right-clicking selects a cell *and* copies in the value. Initially the value is blank, and attempts to paste a blank value will have no effect.

Control-L will refresh the display, recalculating field widths to fit the current entries.

In the default mode the column widths are chosen to fit the contents of each column, with a default of 10 characters for empty columns. you can specify fixed column widths by setting option `de.cellwidth` to the required fixed width (in characters). (set it to zero to return to variable widths). The displayed width of any field is limited to 600 pixels (and by the window width).

[vi](#), [edit](#): edit uses `dataentry` to edit data frames.

Examples

```
# call data entry with variables x and y
## Not run: data.entry(x, y)
```

debugcall

Debug a Call

Description

Set or unset debugging flags based on a call to a function. Takes into account S3/S4 method dispatch based on the classes of the arguments in the call.

Usage

```
debugcall(call, once = FALSE)
undebgcall(call)
```

Arguments

| | |
|------|-------------------------------------------------------------------------------------------------|
| call | An R expression calling a function. The called function will be debugged. See Details. |
| once | logical; if TRUE, debugging only occurs once, as via <code>debugonce</code> . Defaults to FALSE |

Details

`debugcall` debugs the non-generic function, S3 method or S4 method that would be called by evaluating `call`. Thus, the user does not need to specify the signature when debugging methods. Although the call is actually to the generic, it is the method that is debugged, not the generic, except for non-standard S3 generics (see [isS3stdGeneric](#)).

Value

`debugcall` invisibly returns the debugged call expression.

Note

Non-standard evaluation is used to retrieve the `call` (via [substitute](#)). For this reason, passing a variable containing a call expression, rather than the call expression itself, will not work.

See Also

[debug](#) for the primary debugging interface

Examples

```
## Not run:
## Evaluate call after setting debugging
##
f <- factor(1:10)
res <- eval(debugcall(summary(f)))

## End(Not run)
```

debugger

Post-Mortem Debugging

Description

Functions to dump the evaluation environments (frames) and to examine dumped frames.

Usage

```
dump.frames(dumpto = "last.dump", to.file = FALSE,
            include.GlobalEnv = FALSE)
debugger(dump = last.dump)

limitedLabels(value, maxwidth = getOption("width") - 5L)
```

Arguments

| | |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dumpto</code> | a character string. The name of the object or file to dump to. |
| <code>to.file</code> | logical. Should the dump be to an R object or to a file? |
| <code>include.GlobalEnv</code> | logical indicating if a <i>copy</i> of the <code>.GlobalEnv</code> environment should be included in addition to the <code>sys.frames()</code> . Will be particularly useful when used in a batch job. |
| <code>dump</code> | an R dump object created by <code>dump.frames</code> . |
| <code>value</code> | a <i>list</i> of <i>calls</i> to be formatted, e.g., for user menus. |
| <code>maxwidth</code> | optional length to which to trim the result of <code>limitedLabels()</code> ; values smaller than 40 or larger than 1000 are winsorized. |

Details

To use post-mortem debugging, set the option `error` to be a call to `dump.frames`. By default this dumps to an R object `last.dump` in the workspace, but it can be set to dump to a file (a dump of the object produced by a call to [save](#)). The dumped object contains the call stack, the active environments and the last error message as returned by [geterrmessage](#).

When dumping to file, `dumpto` gives the name of the dumped object and the file name has `'.rda'` appended.

A dump object of class `"dump.frames"` can be examined by calling `debugger`. This will give the error message and a list of environments from which to select repeatedly. When an environment is selected, it is copied and the [browser](#) called from within the copy. Note that not all the information in the original frame will be available, e.g. promises which have not yet been evaluated and the contents of any `...` argument.

If `dump.frames` is installed as the error handler, execution will continue even in non-interactive sessions. See the examples for how to dump and then quit.

`limitedLabels(v)` takes a *list* of calls whose elements may have a `srcref` attribute and returns a vector that pastes a formatted version of those attributes onto the formatted version of the elements, all finally [strtrim](#)()med to `maxwidth`.

Value

Invisible NULL.

Note

Functions such as `sys.parent` and `environment` applied to closures will not work correctly inside debugger.

If the error occurred when computing the default value of a formal argument the debugger will report “recursive default argument reference” when trying to examine that environment.

Of course post-mortem debugging will not work if R is too damaged to produce and save the dump, for example if it has run out of workspace.

`browser` for the actions available at the Browse prompt.

`options` for setting error options; `recover` is an interactive debugger working similarly to debugger but directly after the error occurs.

Examples

```
## Not run:
options(error = quote(dump.frames("testdump", TRUE)))

f <- function() {
  g <- function() stop("test dump.frames")
  g()
}
f() # will generate a dump on file "testdump.rda"
options(error = NULL)
```

```
## possibly in another R session
load("testdump.rda")
debugger(testdump)
Available environments had calls:
1: f()
2: g()
3: stop("test dump.frames")
```

```
Enter an environment number, or 0 to exit
Selection: 1
Browsing in the environment with call:
f()
Called from: debugger.look(ind)
Browse[1]> ls()
[1] "g"
Browse[1]> g
function() stop("test dump.frames")
<environment: 759818>
Browse[1]>
```

```

Available environments had calls:
1: f()
2: g()
3: stop("test dump.frames")

Enter an environment number, or 0 to exit
Selection: 0

## A possible setting for non-interactive sessions
options(error = quote({dump.frames(to.file = TRUE); q(status = 1)}))

## End(Not run)

```

demo

Demonstrations of R Functionality

Description

`demo` is a user-friendly interface to running some demonstration R scripts. `demo()` gives the list of available topics.

Usage

```

demo(topic, package = NULL, lib.loc = NULL,
      character.only = FALSE, verbose = getOption("verbose"),
      type = c("console", "html"), echo = TRUE,
      ask = getOption("demo.ask"),
      encoding = getOption("encoding"))

```

Arguments

| | |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>topic</code> | the topic which should be demonstrated, given as a name or literal character string, or a character string, depending on whether <code>character.only</code> is FALSE (default) or TRUE. If omitted, the list of available topics is displayed. |
| <code>package</code> | a character vector giving the packages to look into for demos, or NULL. By default, all packages in the search path are used. |
| <code>lib.loc</code> | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries. |
| <code>character.only</code> | logical; if TRUE, use <code>topic</code> as character string. |
| <code>verbose</code> | a logical. If TRUE, additional diagnostics are printed. |
| <code>type</code> | character: whether to show output in the console or a browser (using the dynamic help system). The latter is honored only in interactive sessions and if the knitr package is installed. Several other arguments are silently ignored in that case, including <code>lib.loc</code> . |
| <code>echo</code> | a logical. If TRUE, show the R input when sourcing. |

| | |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ask | a logical (or "default") indicating if <code>devAskNewPage</code> (ask = TRUE) should be called before graphical output happens from the demo code. The value "default" (the factory-fresh default) means to ask if echo == TRUE and the graphics device appears to be interactive. This parameter applies both to any currently opened device and to any devices opened by the demo code. If this is evaluated to TRUE and the session is interactive , the user is asked to press RETURN to start. |
| encoding | See source . If the package has a declared encoding, that takes preference. |

Details

If no topics are given, demo lists the available demos. For type = "console", the corresponding information is returned in an object of class "packageIQR".

See Also

[source](#) and `devAskNewPage` which are called by demo. [example](#) to run code in the Examples section of help pages.

Examples

```
demo() # for attached packages

## All available demos:
demo(package = .packages(all.available = TRUE))

## Display a demo, pausing between pages
demo(lm.glm, package = "stats", ask = TRUE)

## Display it without pausing
demo(lm.glm, package = "stats", ask = FALSE)

## Not run:
ch <- "scoping"
demo(ch, character = TRUE)

## End(Not run)

## Find the location of a demo
system.file("demo", "lm.glm.R", package = "stats")
```

DLL.version

DLL Version Information on MS Windows

Description

On MS Windows only, return the version of the package and the version of R used to build the DLL, if available.

Usage

```
DLL.version(path)
```

Arguments

path character vector of length one giving the complete path to the DLL.

Value

If the DLL does not exist, NULL.

A character vector of length two, giving the DLL version and the version of R used to build the DLL. If the information is not available, the corresponding string is empty.

Note

This is only available on Windows.

Examples

```
if(.Platform$OS.type == "windows") withAutoprint({
  DLL.version(file.path(R.home("bin"), "R.dll"))
  DLL.version(file.path(R.home(), "library/stats/libs", .Platform$r_arch, "stats.dll"))
})
```

download.file

Download File from the Internet

Description

This function can be used to download a file from the Internet.

Usage

```
download.file(url, destfile, method, quiet = FALSE, mode = "w",
              cacheOK = TRUE,
              extra = getOption("download.file.extra"),
              headers = NULL, ...)
```

Arguments

url a [character](#) string (or longer vector for the "libcurl" method) naming the URL of a resource to be downloaded.

destfile a character string (or vector, see the url argument) with the file path where the downloaded file is to be saved. Tilde-expansion is performed.

| | |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| method | Method to be used for downloading files. Current download methods are "internal", "libcurl", "wget", "curl" and "wininet" (Windows only), and there is a value "auto": see 'Details' and 'Note'. The method can also be set through the option "download.file.method": see options() . |
| quiet | If TRUE, suppress status messages (if any), and the progress bar. |
| mode | character. The mode with which to write the file. Useful values are "w", "wb" (binary), "a" (append) and "ab". Not used for methods "wget" and "curl". See also 'Details', notably about using "wb" for Windows. |
| cacheOK | logical. Is a server-side cached value acceptable? |
| extra | character vector of additional command-line arguments for the "wget" and "curl" methods. |
| headers | named character vector of additional HTTP headers to use in HTTP[S] requests. It is ignored for non-HTTP[S] URLs. The User-Agent header taken from the HTTPUserAgent option (see options) is automatically used as the first header. |
| ... | allow additional arguments to be passed, unused. |

Details

The function `download.file` can be used to download a single file as described by `url` from the internet and store it in `destfile`.

The `url` must start with a scheme such as 'http://', 'https://' or 'file://'. Which methods support which schemes varies by R version, but `method = "auto"` will try to find a method which supports the scheme.

For `method = "auto"` (the default) currently the "internal" method is used for 'file://' URLs and "libcurl" for all others.

Support for method "libcurl" was optional on Windows prior to R 4.2.0: use [capabilities\("libcurl"\)](#) to see if it is supported on an earlier version. It uses an external library of that name (<https://curl.se/libcurl/>) against which R can be compiled.

When method "libcurl" is used, there is support for simultaneous downloads, so `url` and `destfile` can be character vectors of the same length greater than one (but the method has to be specified explicitly and not *via* "auto"). For a single URL and `quiet = FALSE` a progress bar is shown in interactive use.

Nowadays the "internal" method only supports the 'file://' scheme (for which it is the default). On Windows the "wininet" method currently supports 'file://' and (but deprecated with a warning) 'http://' and 'https://' schemes.

For methods "wget" and "curl" a system call is made to the tool given by `method`, and the respective program must be installed on your system and be in the search path for executables. They will block all other activity on the R process until they complete: this may make a GUI unresponsive.

`cacheOK = FALSE` is useful for 'http://' and 'https://' URLs: it will attempt to get a copy directly from the site rather than from an intermediate cache. It is used by [available.packages](#).

The "libcurl" and "wget" methods follow 'http://' and 'https://' redirections to any scheme they support. (For method "curl" use argument `extra = "-L"`. To disable redirection in wget, use `extra = "--max-redirect=0"`.) The "wininet" method supports some redirections but not all. (For method "libcurl", messages will quote the endpoint of redirections.)

See [url](#) for how 'file://' URLs are interpreted, especially on Windows. The "internal" and "wininet" methods do not percent-decode, but the "libcurl" and "curl" methods do: method "wget" does not support them.

Most methods do not percent-encode special characters such as spaces in URLs (see [URLencode](#)), but it seems the "wininet" method does.

The remaining details apply to the "wininet" and "libcurl" methods only.

The timeout for many parts of the transfer can be set by the option `timeout` which defaults to 60 seconds. This is often insufficient for downloads of large files (50MB or more) and so should be increased when `download.file` is used in packages to do so. Note that the user can set the default timeout by the environment variable `R_DEFAULT_INTERNET_TIMEOUT` in recent versions of R, so to ensure that this is not decreased packages should use something like

```
options(timeout = max(300, getOption("timeout")))
```

(It is unrealistic to require download times of less than 1s/MB.)

The level of detail provided during transfer can be set by the `quiet` argument and the `internet.info` option: the details depend on the platform and scheme. For the "libcurl" method values of the option less than 2 give verbose output.

A progress bar tracks the transfer platform-specifically:

On Windows If the file length is known, the full width of the bar is the known length. Otherwise the initial width represents 100 Kbytes and is doubled whenever the current width is exceeded. (In non-interactive use this uses a text version. If the file length is known, an equals sign represents 2% of the transfer completed: otherwise a dot represents 10Kb.)

On a Unix-alike If the file length is known, an equals sign represents 2% of the transfer completed: otherwise a dot represents 10Kb.

The choice of binary transfer (mode = "wb" or "ab") is important on Windows, since unlike Unix-alikes it does distinguish between text and binary files and for text transfers changes '\n' line endings to '\r\n' (aka 'CRLF').

On Windows, if mode is not supplied ([missing\(\)](#)) and `url` ends in one of '.gz', '.bz2', '.xz', '.tgz', '.zip', '.jar', '.rda', '.rds', '.RData' or '.pdf', mode = "wb" is set so that a binary transfer is done to help unwary users.

Code written to download binary files must use mode = "wb" (or "ab"), but the problems incurred by a text transfer will only be seen on Windows.

Value

An (invisible) integer code, 0 for success and non-zero for failure. For the "wget" and "curl" methods this is the status code returned by the external program. The "internal" method can return 1, but will in most cases throw an error.

What happens to the destination file(s) in the case of error depends on the method and R version. Currently the "internal", "wininet" and "libcurl" methods will remove the file if the URL is unavailable except when mode specifies appending when the file should be unchanged.

Setting Proxies

For the Windows-only method "wininet", the 'Internet Options' of the system are used to choose proxies and so on; these are set in the Control Panel and are those used for system browsers.

For the "libcurl" and "curl" methods, proxies can be set *via* the environment variables `http_proxy` or `ftp_proxy`. See <https://curl.se/libcurl/c/libcurl-tutorial.html> for further details.

Secure URLs

Methods which access 'https://' and (where supported) 'ftps://' URLs should try to verify the site certificates. This is usually done using the CA root certificates installed by the OS (although we have seen instances in which these got removed rather than updated). For further information see <https://curl.se/docs/sslcerts.html>.

On Windows with `method = "libcurl"`, the CA root certificates are provided by the OS when R was linked with libcurl with Schannel enabled, which is the current default in Rtools. This can be verified by checking that `libcurlVersion()` returns a version string containing "Schannel". If it does not, for verification to be on the environment variable `CURL_CA_BUNDLE` must be set to a path to a certificate bundle file, usually named 'ca-bundle.crt' or 'curl-ca-bundle.crt'. (This is normally done automatically for a binary installation of R, which installs '`R_HOME/etc/curl-ca-bundle.crt`' and sets `CURL_CA_BUNDLE` to point to it if that environment variable is not already set.) For an updated certificate bundle, see <https://curl.se/docs/sslcerts.html>. Currently one can download a copy from <https://raw.githubusercontent.com/bagder/ca-bundle/master/ca-bundle.crt> and set `CURL_CA_BUNDLE` to the full path to the downloaded file.

On Windows with `method = "libcurl"`, when R was linked with libcurl with Schannel enabled, the connection fails if it cannot be established that the certificate has not been revoked. Some MITM proxies present particularly in corporate environments do not work with this behavior. It can be changed by setting environment variable `R_LIBCURL_SSL_REVOKE_BEST_EFFORT` to `TRUE`, with the consequence of reducing security.

Note that the root certificates used by R may or may not be the same as used in a browser, and indeed different browsers may use different certificate bundles (there is typically a build option to choose either their own or the system ones).

Good practice

Setting the method should be left to the end user. Neither of the `wget` nor `curl` commands is widely available: you can check if one is available *via* `Sys.which`, and should do so in a package or script.

If you use `download.file` in a package or script, you must check the return value, since it is possible that the download will fail with a non-zero status but not an R error.

The supported methods do change: method `libcurl` was introduced in R 3.2.0 and was optional on Windows until R 4.2.0 – use `capabilities("libcurl")` in a program to see if it is available.

'ftp://' URLs

Most modern browsers do not support such URLs, and 'https://' ones are much preferred for use in R. 'ftps://' URLs have always been rare, and are nowadays even less supported.

It is intended that R will continue to allow such URLs for as long as libcurl does, but as they become rarer this is increasingly untested. What ‘protocols’ the version of libcurl being used supports can be seen by calling `libcurlVersion()`.

These URLs are accessed using the FTP protocol which has a number of variants. One distinction is between ‘active’ and ‘(extended) passive’ modes; which is used is chosen by the client. The “libcurl” method uses passive mode which was almost universally used by browsers before they dropped support altogether.

Note

Files of more than 2GB are supported on 64-bit builds of R; they may be truncated on some 32-bit builds.

Methods “wget” and “curl” are mainly for historical compatibility but provide may provide capabilities not supported by the “libcurl” or “wininet” methods.

Method “wget” can be used with proxy firewalls which require user/password authentication if proper values are stored in the configuration file for wget.

wget (<https://www.gnu.org/software/wget/>) is commonly installed on Unix-alikes (but not macOS). Windows binaries are available from MSYS2 and elsewhere.

curl (<https://curl.se/>) is installed on macOS and increasingly commonly on Unix-alikes. Windows binaries are available at that URL.

Contributed packages **RCurl** and **curl** provide more comprehensive facilities to download from URLs.

download.packages

Download Packages from CRAN-like Repositories

Description

These functions can be used to automatically compare the version numbers of installed packages with the newest available version on the repositories and update outdated packages on the fly.

Usage

```
download.packages(pkgs, destdir, available = NULL,
                  repos = getOption("repos"),
                  contriburl = contrib.url(repos, type),
                  method, type = getOption("pkgType"), ...)
```

Arguments

| | |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pkgs</code> | character vector of the names of packages whose latest available versions should be downloaded from the repositories. |
| <code>destdir</code> | directory where downloaded packages are to be stored. |
| <code>available</code> | an object as returned by available.packages listing packages available at the repositories, or <code>NULL</code> which makes an internal call to <code>available.packages</code> . |
| <code>repos</code> | character vector, the base URL(s) of the repositories to use, i.e., the URL of the CRAN master such as <code>"https://cran.r-project.org"</code> or ones of its mirrors, <code>"https://cloud.r-project.org"</code> . |
| <code>contriburl</code> | URL(s) of the contrib sections of the repositories. Use this argument only if your repository mirror is incomplete, e.g., because you burned only the ‘contrib’ section on a CD. Overrides argument <code>repos</code> . |
| <code>method</code> | Download method, see download.file . |
| <code>type</code> | character string, indicate which type of packages: see install.packages and ‘Details’. |
| <code>...</code> | additional arguments to be passed to download.file and available.packages . |

Details

`download.packages` takes a list of package names and a destination directory, downloads the newest versions and saves them in `destdir`. If the list of available packages is not given as argument, it is obtained from repositories. If a repository is local, i.e. the URL starts with `"file:"`, then the packages are not downloaded but used directly. Both `"file:"` and `"file://"` are allowed as prefixes to a file path. Use the latter only for URLs: see [url](#) for their interpretation. (Other forms of `'file:/'` URLs are not supported.)

For `download.packages`, `type = "both"` looks at source packages only.

Value

A two-column matrix of names and destination file names of those packages successfully downloaded. If packages are not available or there is a problem with the download, suitable warnings are given.

See Also

[available.packages](#), [contrib.url](#).

The main use is by [install.packages](#).

See [download.file](#) for how to handle proxies and other options to monitor file transfers.

The ‘R Installation and Administration’ manual for how to set up a repository.

edit

*Invoke a Text Editor***Description**

Invoke a text editor on an R object.

Usage

```
edit(name, ...)
## Default S3 method:
edit(name = NULL, file = "", title = NULL,
     editor = getOption("editor"), ...)

vi(name = NULL, file = "")
emacs(name = NULL, file = "")
pico(name = NULL, file = "")
xemacs(name = NULL, file = "")
xedit(name = NULL, file = "")
```

Arguments

| | |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| name | a named object that you want to edit. For the default method, if name is missing then the file specified by file is opened for editing. |
| file | a string naming the file to write the edited version to. |
| title | a display name for the object being edited. |
| editor | usually a character string naming (or giving the path to) the text editor you want to use. On Unix the default is set from the environment variables EDITOR or VISUAL if either is set, otherwise vi is used. On Windows it defaults to "internal", the script editor. On the macOS GUI the argument is ignored and the document editor is always used. editor can also be an R function, in which case it is called with the arguments name, file, and title. Note that such a function will need to independently implement all desired functionality. |
| ... | further arguments to be passed to or from methods. |

Details

edit invokes the text editor specified by editor with the object name to be edited. It is a generic function, currently with a default method and one for data frames and matrices.

data.entry can be used to edit data, and is used by edit to edit matrices and data frames on systems for which data.entry is available.

It is important to realize that edit does not change the object called name. Instead, a copy of name is made and it is that copy which is changed. Should you want the changes to apply to the object name you must assign the result of edit to name. (Try [fix](#) if you want to make permanent changes to an object.)

In the form `edit(name)`, `edit` deparses `name` into a temporary file and invokes the editor `editor` on this file. Quitting from the editor causes file to be parsed and that value returned. Should an error occur in parsing, possibly due to incorrect syntax, no value is returned. Calling `edit()`, with no arguments, will result in the temporary file being reopened for further editing.

Note that deparsing is not perfect, and the object recreated after editing can differ in subtle ways from that deparsed: see `dput` and `.deparseOpts`. (The deparse options used are the same as the defaults for `dump`.) Editing a function will preserve its environment. See `edit.data.frame` for further changes that can occur when editing a data frame or matrix.

Currently only the internal editor in Windows makes use of the `title` option; it displays the given name in the window header.

Note

The functions `vi`, `emacs`, `pico`, `xemacs`, `xedit` rely on the corresponding editor being available and being on the path. This is system-dependent.

See Also

`edit.data.frame`, `data.entry`, `fix`.

Examples

```
## Not run:
# use xedit on the function mean and assign the changes
mean <- edit(mean, editor = "xedit")

# use vi on mean and write the result to file mean.out
vi(mean, file = "mean.out")

## End(Not run)
```

edit.data.frame

Edit Data Frames and Matrices

Description

Use data editor on data frame or matrix contents.

Usage

```
## S3 method for class 'data.frame'
edit(name, factor.mode = c("character", "numeric"),
      edit.row.names = any(row.names(name) != 1:nrow(name)), ...)

## S3 method for class 'matrix'
edit(name, edit.row.names = !is.null(dn[[1]]), ...)
```

Arguments

| | |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>name</code> | A data frame or (numeric, logical or character) matrix. |
| <code>factor.mode</code> | How to handle factors (as integers or using character levels) in a data frame. Can be abbreviated. |
| <code>edit.row.names</code> | logical. Show the row names (if they exist) be displayed as a separate editable column? It is an error to ask for this on a matrix with NULL row names. |
| <code>...</code> | further arguments passed to or from other methods. |

Details

At present, this only works on simple data frames containing numeric, logical or character vectors and factors, and numeric, logical or character matrices. Any other mode of matrix will give an error, and a warning is given when the matrix has a class (which will be discarded).

Data frame columns are coerced on input to *character* unless numeric (in the sense of `is.numeric`), logical or factor. A warning is given when classes are discarded. Special characters (tabs, non-printing ASCII, etc.) will be displayed as escape sequences.

Factors columns are represented in the spreadsheet as either numeric vectors (which are more suitable for data entry) or character vectors (better for browsing). After editing, vectors are padded with NA to have the same length and factor attributes are restored. The set of factor levels can not be changed by editing in numeric mode; invalid levels are changed to NA and a warning is issued. If new factor levels are introduced in character mode, they are added at the end of the list of levels in the order in which they encountered.

It is possible to use the data-editor's facilities to select the mode of columns to swap between numerical and factor columns in a data frame. Changing any column in a numerical matrix to character will cause the result to be coerced to a character matrix. Changing the mode of logical columns is not supported.

For a data frame, the row names will be taken from the original object if `edit.row.names = FALSE` and the number of rows is unchanged, and from the edited output if `edit.row.names = TRUE` and there are no duplicates. (If the `row.names` column is incomplete, it is extended by entries like `row223`.) In all other cases the row names are replaced by `seq(length = nrow)`.

For a matrix, `colnames` will be added (of the form `col17`) if needed. The `rownames` will be taken from the original object if `edit.row.names = FALSE` and the number of rows is unchanged (otherwise NULL), and from the edited output if `edit.row.names = TRUE`. (If the `row.names` column is incomplete, it is extended by entries like `row223`.)

Editing a matrix or data frame will lose all attributes apart from the row and column names.

Value

The edited data frame or matrix.

Note

`fix(dataframe)` works for in-place editing by calling this function.

If the data editor is not available, a dump of the object is presented for editing using the default method of `edit`.

At present the data editor is limited to 65535 rows.

```
## Not run:
edit(InsectSprays)
edit(InsectSprays, factor.mode = "numeric")

## End(Not run)
```

example

*Run an Examples Section from the Online Help***Description**

Run all the R code from the **Examples** part of R's online help topic topic, with possible exceptions due to \dontrun, \dontshow, and \donttest tags, see 'Details' below.

Usage

```
example(topic, package = NULL, lib.loc = NULL,
        character.only = FALSE, give.lines = FALSE, local = FALSE,
        type = c("console", "html"), echo = TRUE,
        verbose = getOption("verbose"),
        setRNG = FALSE, ask = getOption("example.ask"),
        prompt.prefix = abbreviate(topic, 6),
        catch.aborts = FALSE,
        run.dontrun = FALSE, run.donttest = interactive())
```

Arguments

| | |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| topic | name or literal character string: the online help topic the examples of which should be run. |
| package | a character vector giving the package names to look into for the topic, or NULL (the default), when all packages on the search path are used. |
| lib.loc | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries. |
| character.only | a logical indicating whether topic can be assumed to be a character string. |
| give.lines | logical: if true, the <i>lines</i> of the example source code are returned as a character vector. |

| | |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| local | logical: if TRUE evaluate locally, if FALSE evaluate in the workspace. |
| type | character: whether to show output in the console or a browser (using the dynamic help system). The latter is honored only in interactive sessions and if the knitr package is installed. Several other arguments are silently ignored in that case, including <code>setRNG</code> and <code>lib.loc</code> . |
| echo | logical; if TRUE, show the R input when sourcing. |
| verbose | logical; if TRUE, show even more when running example code. |
| setRNG | logical or expression; if not FALSE, the random number generator state is saved, then initialized to a specified state, the example is run and the (saved) state is restored. <code>setRNG = TRUE</code> sets the same state as R CMD check does for running a package's examples. This is currently equivalent to <code>setRNG = {RNGkind("default", "default", "default"); set.seed(1)}</code> . |
| ask | logical (or "default") indicating if devAskNewPage (ask = TRUE) should be called before graphical output happens from the example code. The value "default" (the factory-fresh default) means to ask if echo is true and the graphics device appears to be interactive. This parameter applies both to any currently opened device and to any devices opened by the example code. |
| prompt.prefix | character; prefixes the prompt to be used if echo is true (as it is by default). |
| catch.aborts | logical, passed on to source (), indicating that "abort"ing errors should be caught. |
| run.dontrun | logical indicating that <code>\dontrun</code> should be ignored, i.e., do run the enclosed code. |
| run.donttest | logical indicating that <code>\donttest</code> should be ignored, i.e., do run the enclosed code. |

Details

If `lib.loc` is not specified, the packages are searched for amongst those already loaded, then in the libraries given by `.libPaths()`. If `lib.loc` is specified, packages are searched for only in the specified libraries, even if they are already loaded from another library. The search stops at the first package found that has help on the topic.

An attempt is made to load the package before running the examples, but this will not replace a package loaded from another location.

If `local = TRUE` objects are not created in the workspace and so not available for examination after example completes: on the other hand they cannot overwrite objects of the same name in the workspace.

As detailed in the 'Writing R Extensions' manual, the author of the help page can tag parts of the examples with the following exception rules:

`\dontrun` encloses code that should not be run.

`\dontshow` encloses code that is invisible on help pages, but will be run both by the package checking tools, and the `example()` function. This was previously `\testonly`, and that form is still accepted.

`\donttest` encloses code that typically should be run, but not during package checking. The default `run.donttest = interactive()` leads `example()` use in other help page examples to skip `\donttest` sections appropriately.

The additional `\dontdiff` tag (in $R \geq 4.4.0$) produces special comments in the code run by `example` (for `Rdiff`-based testing of example output), but does not affect which code is run or displayed on the help page.

Value

The value of the last evaluated expression, unless `give.lines` is true, where a `character` vector is returned.

[demo](#)

Examples

```
example(InsectSprays)
## force use of the standard package 'stats':
example("smooth", package = "stats", lib.loc = .Library)

## set RNG *before* example as when R CMD check is run:

r1 <- example(quantile, setRNG = TRUE)
x1 <- rnorm(1)
u <- runif(1)
## identical random numbers
r2 <- example(quantile, setRNG = TRUE)
x2 <- rnorm(1)
stopifnot(identical(r1, r2))
## but x1 and x2 differ since the RNG state from before example()
## differs and is restored!
x1; x2

## Exploring examples code:
## How large are the examples of "lm..." functions?
lmex <- sapply(apropos("^lm", mode = "function"),
              example, character.only = TRUE, give.lines = TRUE)
lengths(lmex)
```

file.edit

Edit One or More Files

Description

Edit one or more files in a text editor.

Usage

```
file.edit(..., title = file, editor = getOption("editor"),
          fileEncoding = "")
```

Arguments

| | |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| ... | one or more character vectors containing the names of the files to be displayed. These will be tilde-expanded: see path.expand . |
| title | the title to use in the editor; defaults to the filename. |
| editor | the text editor to be used, usually as a character string naming (or giving the path to) the text editor you want to use See ‘Details’. |
| fileEncoding | the encoding to assume for the file: the default is to assume the native encoding. See the ‘Encoding’ section of the help for file . |

Details

The behaviour of this function is very system-dependent. Currently files can be opened only one at a time on Unix; on Windows, the internal editor allows multiple files to be opened, but has a limit of 50 simultaneous edit windows.

The title argument is used for the window caption in Windows, and is currently ignored on other platforms.

Any error in re-encoding the files to the native encoding will cause the function to fail.

The default for editor is system-dependent. On Windows it defaults to "internal", the script editor, and in the macOS GUI the document editor is used whatever the value of editor. On Unix the default is set from the environment variables EDITOR or VISUAL if either is set, otherwise vi is used.

editor can also be an R function, in which case it is called with the arguments name, file, and title. Note that such a function will need to independently implement all desired functionality.

On Windows, UTF-8-encoded paths not valid in the current locale can be used.

file_test

*Shell-style Tests on Files***Description**

Utility for shell-style file tests.

Usage

```
file_test(op, x, y)
```

Arguments

| | |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| op | a character string specifying the test to be performed. Unary tests (only x is used) are "-f" (existence and not being a directory), "-d" (existence and directory), "-L" or "-h" (existence and symbolic link), "-x" (executable as a file or searchable as a directory), "-w" (writable) and "-r" (readable). Binary tests are "-nt" (strictly newer than, using the modification dates) and "-ot" (strictly older than): in both cases the test is false unless both files exist. |
| x, y | character vectors giving file paths. |

Details

'Existence' here means being on the file system and accessible by the stat system call (or a 64-bit extension) – on a Unix-alike this requires execute permission on all of the directories in the path that leads to the file, but no permissions on the file itself.

For the meaning of "-x" on Windows see [file.access](#).

See Also

[file.exists](#) which only tests for existence (test -e on some systems) but not for not being a directory.

[file.path](#), [file.info](#)

Examples

dir <- file.path(R.home(), "library", "stats")
file_test("-d", dir)
file_test("-nt", file.path(dir, "R"), file.path(dir, "demo"))
```

| | |
|----------------|------------------------------------|
| findCRANmirror | <i>Find CRAN Mirror Preference</i> |
|----------------|------------------------------------|

Description

Find out if a CRAN mirror has been selected for the current session.

Usage

```
findCRANmirror(type = c("src", "web"))
```

Arguments

| | |
|------|------------------------------------------------------------------|
| type | Is the mirror to be used for package sources or web information? |
|------|------------------------------------------------------------------|

Details

Find out if a CRAN mirror has been selected for the current session. If so, return its URL else return `"https://CRAN.R-project.org"`.

The mirror is looked for in several places.

- The value of the environment variable `R_CRAN_SRC` or `R_CRAN_WEB` (depending on type), if set.
- An entry in `getOption("repos")` named 'CRAN' which is not the default `"@CRAN@"`.
- The 'CRAN' URL entry in the 'repositories' file (see [setRepositories](#)), if it is not the default `"@CRAN@"`.

The two types allow for partial local CRAN mirrors, for example those mirroring only the package sources where `getOption("repos")` might point to the partial mirror and `R_CRAN_WEB` point to a full (remote) mirror.

Value

A character string.

See Also

[setRepositories](#), [chooseCRANmirror](#)

Examples

```
c(findCRANmirror("src"), findCRANmirror("web"))

Sys.setenv(R_CRAN_WEB = "https://cloud.r-project.org")
c(findCRANmirror("src"), findCRANmirror("web"))
```

| | |
|-------------|------------------------------------------------------------------------------|
| findLineNum | <i>Find the Location of a Line of Source Code, or Set a Breakpoint There</i> |
|-------------|------------------------------------------------------------------------------|

Description

These functions locate objects containing particular lines of source code, using the information saved when the code was parsed with `keep.source = TRUE`.

Usage

```
findLineNum(srcfile, line, nameonly = TRUE,
            envir = parent.frame(), lastenv)

setBreakpoint(srcfile, line, nameonly = TRUE,
              envir = parent.frame(), lastenv, verbose = TRUE,
              tracer, print = FALSE, clear = FALSE, ...)
```

Arguments

| | |
|----------|---------------------------------------------------------------------------------------------------------------------------|
| srcfile | The name of the file containing the source code. |
| line | The line number within the file. See Details for an alternate way to specify this. |
| nameonly | If TRUE (the default), we require only a match to <code>basename(srcfile)</code> , not to the full path. |
| envir | Where do we start looking for function objects? |
| lastenv | Where do we stop? See the Details. |
| verbose | Should we print information on where breakpoints were set? |
| tracer | An optional tracer function to pass to trace . By default, a call to browser is inserted. |
| print | The print argument to pass to trace . |
| clear | If TRUE, call untrace rather than trace . |
| ... | Additional arguments to pass to trace . |

Details

The `findLineNum` function searches through all objects in environment `envir`, its parent, grandparent, etc., all the way back to `lastenv`.

`lastenv` defaults to the global environment if `envir` is not specified, and to the root environment [emptyenv\(\)](#) if `envir` is specified. (The first default tends to be quite fast, and will usually find all user code other than S4 methods; the second one is quite slow, as it will typically search all attached system libraries.)

For convenience, `envir` may be specified indirectly: if it is not an environment, it will be replaced with `environment(envir)`.

`setBreakpoint` is a simple wrapper function for [trace](#) and [untrace](#). It will set or clear breakpoints at the locations found by `findLineNum`.

The `srcfile` is normally a filename entered as a character string, but it may be a "`srcfile`" object, or it may include a suffix like "`filename.R#nn`", in which case the number `nn` will be used as a default value for `line`.

As described in the description of the `where` argument on the man page for `trace`, the R package system uses a complicated scheme that may include more than one copy of a function in a package. The user will typically see the public one on the search path, while code in the package will see a private one in the package namespace. If you set `envir` to the environment of a function in the package, by default `findLineNum` will find both versions, and `setBreakpoint` will set the breakpoint in both. (This can be controlled using `lastenv`; e.g., `envir = environment(foo)`, `lastenv = globalenv()` will find only the private copy, as the search is stopped before seeing the public copy.)

S version 4 methods are also somewhat tricky to find. They are stored with the generic function, which may be in the **base** or other package, so it is usually necessary to have `lastenv = emptyenv()` in order to find them. In some cases transformations are done by R when storing them and `findLineNum` may not be able to find the original code. Many special cases, e.g. methods on primitive generics, are not yet supported.

Value

`findLineNum` returns a list of objects containing location information. A print method is defined for them.

`setBreakpoint` has no useful return value; it is called for the side effect of calling `trace` or `untrace`.

`trace`

Examples

```
## Not run:
# Find what function was defined in the file mysource.R at line 100:
findLineNum("mysource.R#100")

# Set a breakpoint in both copies of that function, assuming one is in the
# same namespace as myfunction and the other is on the search path
setBreakpoint("mysource.R#100", envir = myfunction)

## End(Not run)
```

`fix`*Fix an Object*

Description

`fix` invokes [edit](#) on `x` and then assigns the new (edited) version of `x` in the user's workspace.

Usage

```
fix(x, ...)
```

Arguments

| | |
|------------------|-----------------------------------------------------------|
| <code>x</code> | the name of an R object, as a name or a character string. |
| <code>...</code> | arguments to pass to editor: see edit . |

Details

The name supplied as `x` need not exist as an R object, in which case a function with no arguments and an empty body is supplied for editing.

Editing an R object may change it in ways other than are obvious: see the comment under [edit](#). See [edit.data.frame](#) for changes that can occur when editing a data frame or matrix.

See Also

[edit](#), [edit.data.frame](#)

Examples

```
## Not run:
## Assume 'my.fun' is a user defined function :
fix(my.fun)
## now my.fun is changed
## Also,
fix(my.data.frame) # calls up data editor
fix(my.data.frame, factor.mode="char") # use of ...

## End(Not run)
```

| | |
|---------------|----------------------------------|
| flush.console | <i>Flush Output to a Console</i> |
|---------------|----------------------------------|

Description

This does nothing except on console-based versions of R. On the macOS and Windows GUIs, it ensures that the display of output in the console is current, even if output buffering is on.

Usage

```
flush.console()
```

| | |
|--------|-------------------------------------------|
| format | <i>Format Unordered and Ordered Lists</i> |
|--------|-------------------------------------------|

Description

Format unordered (itemize) and ordered (enumerate) lists.

Usage

```
formatUL(x, label = "*", offset = 0,
         width = 0.9 * getOption("width"))
formatOL(x, type = "arabic", offset = 0, start = 1,
         width = 0.9 * getOption("width"))
```

Arguments

| | |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x | a character vector of list items. |
| label | a character string used for labelling the items. |
| offset | a non-negative integer giving the offset (indentation) of the list. |
| width | a positive integer giving the target column for wrapping lines in the output. |
| type | a character string specifying the ‘type’ of the labels in the ordered list. If "arabic" (default), arabic numerals are used. For "Alph" or "alph", single upper or lower case letters are employed (in this case, the number of the last item must not exceed 26). Finally, for "Roman" or "roman", the labels are given as upper or lower case roman numerals (with the number of the last item maximally 3999). type can be given as a unique abbreviation of the above, or as one of the HTML style tokens "1" (arabic), "A"/"a" (alphabetic), or "I"/"i" (roman), respectively. |
| start | a positive integer specifying the starting number of the first item in an ordered list. |

Value

A character vector with the formatted entries.

See Also

[formatDL](#) for formatting description lists.

Examples

```
## A simpler recipe.
x <- c("Mix dry ingredients thoroughly.",
      "Pour in wet ingredients.",
      "Mix for 10 minutes.",
      "Bake for one hour at 300 degrees.")
## Format and output as an unordered list.
writeLines(formatUL(x))
## Format and output as an ordered list.
writeLines(formatOL(x))
## Ordered list using lower case roman numerals.
writeLines(formatOL(x, type = "i"))
## Ordered list using upper case letters and some offset.
writeLines(formatOL(x, type = "A", offset = 5))
```

getAnywhere

Retrieve an R Object, Including from a Namespace

Description

These functions locate all objects with name matching their argument, whether visible on the search path, registered as an S3 method or in a namespace but not exported. `getAnywhere()` returns the objects and `argsAnywhere()` returns the arguments of any objects that are functions.

Usage

```
getAnywhere(x)
argsAnywhere(x)
```

Arguments

`x` a character string or name.

Details

These functions look at all loaded namespaces, whether or not they are associated with a package on the search list.

They do not search literally “anywhere”: for example, local evaluation frames and namespaces that are not loaded will not be searched.

Where functions are found as registered S3 methods, an attempt is made to find which namespace registered them. This may not be correct, especially if namespaces have been unloaded.

Value

For `getAnywhere()` an object of class "getAnywhere". This is a list with components

| | |
|----------------------|--------------------------------------------------------------|
| <code>name</code> | the name searched for |
| <code>objs</code> | a list of objects found |
| <code>where</code> | a character vector explaining where the object(s) were found |
| <code>visible</code> | logical: is the object visible |
| <code>dups</code> | logical: is the object identical to one earlier in the list. |

In computing whether objects are identical, their environments are ignored.

Normally the structure will be hidden by the `print` method. There is a `[` method to extract one or more of the objects found.

For `argsAnywhere()` one or more argument lists as returned by [args](#).

See Also

[getS3method](#) to find the method which would be used: this might not be the one of those returned by `getAnywhere` since it might have come from a namespace which was unloaded or be registered under another name.

[get](#), [getFromNamespace](#), [args](#)

Examples

```
getAnywhere("format.dist")
getAnywhere("simpleLoess") # not exported from stats
argsAnywhere(format.dist)
```

| | |
|-------------------------------|----------------------------------------------------|
| <code>getFromNamespace</code> | <i>Utility Functions for Developing Namespaces</i> |
|-------------------------------|----------------------------------------------------|

Description

Utility functions to access and replace the non-exported functions in a namespace, for use in developing packages with namespaces.

They should not be used in production code (except perhaps `assignInMyNamespace`, but see the 'Note').

Usage

```
getFromNamespace(x, ns, pos = -1, envir = as.environment(pos))

assignInNamespace(x, value, ns, pos = -1,
                  envir = as.environment(pos))

assignInMyNamespace(x, value)

fixInNamespace(x, ns, pos = -1, envir = as.environment(pos), ...)
```

Arguments

| | |
|--------------------|-------------------------------------------------------------|
| <code>x</code> | an object name (given as a character string). |
| <code>value</code> | an R object. |
| <code>ns</code> | a namespace, or character string giving the namespace. |
| <code>pos</code> | where to look for the object: see get . |
| <code>envir</code> | an alternative way to specify an environment to look in. |
| <code>...</code> | arguments to pass to the editor: see edit . |

Details

`assignInMyNamespace` is intended to be called from functions within a package, and chooses the namespace as the environment of the function calling it.

The namespace can be specified in several ways. Using, for example, `ns = "stats"` is the most direct, but a loaded package can be specified via any of the methods used for [get](#): `ns` can also be the environment printed as `'<namespace:foo>'`.

`getFromNamespace` is similar to (but predates) the `:::` operator: it is more flexible in how the namespace is specified.

`fixInNamespace` invokes [edit](#) on the object named `x` and assigns the revised object in place of the original object. For compatibility with `fix`, `x` can be unquoted.

Value

`getFromNamespace` returns the object found (or gives an error).

`assignInNamespace`, `assignInMyNamespace` and `fixInNamespace` are invoked for their side effect of changing the object in the namespace.

Warning

`assignInNamespace` should not be used in final code, and will in future throw an error if called from a package. Already certain uses are disallowed.

Note

`assignInNamespace`, `assignInMyNamespace` and `fixInNamespace` change the copy in the namespace, but not any copies already exported from the namespace, in particular an object of that name in the package (if already attached) and any copies already imported into other namespaces. They are really intended to be used *only* for objects which are not exported from the namespace. They do attempt to alter a copy registered as an S3 method if one is found.

They can only be used to change the values of objects in the namespace, not to create new objects.

[get](#), [fix](#), [getS3method](#)

Examples

```
getFromNamespace("findGeneric", "utils")
## Not run:
fixInNamespace("predict.ppr", "stats")
stats::predict.ppr
getS3method("predict", "ppr")
## alternatively
fixInNamespace("predict.ppr", pos = 3)
fixInNamespace("predict.ppr", pos = "package:stats")

## End(Not run)
```

getParseData

Get Detailed Parse Information from Object

Description

If the "keep.source" option is TRUE, R's parser will attach detailed information on the object it has parsed. These functions retrieve that information.

Usage

```
getParseData(x, includeText = NA)
getParseText(parseData, id)
```

Arguments

| | |
|-------------|---------------------------------------------------------------------------------------------------------------------|
| x | an expression returned from parse , or a function or other object with source reference information |
| includeText | logical; whether to include the text of parsed items in the result |
| parseData | a data frame returned from <code>getParseData</code> |
| id | a vector of item identifiers whose text is to be retrieved |

Details

In version 3.0.0, the R parser was modified to include code written by Romain Francois in his **parser** package. This constructs a detailed table of information about every token and higher level construct in parsed code. This table is stored in the [srcfile](#) record associated with source references in the parsed code, and retrieved by the `getParseData` function.

Value

For `getParseData`:

If parse data is not present, NULL. Otherwise a data frame is returned, containing the following columns:

| | |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| line1 | integer. The line number where the item starts. This is the parsed line number called "parse" in getSrcLocation , which ignores #line directives. |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| | |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| col1 | integer. The column number where the item starts. The first character is column 1. This corresponds to "column" in getSrcLocation . |
| line2 | integer. The line number where the item ends. |
| col2 | integer. The column number where the item ends. |
| id | integer. An identifier associated with this item. |
| parent | integer. The id of the parent of this item. |
| token | character string. The type of the token. |
| terminal | logical. Whether the token is "terminal", i.e. a leaf in the parse tree. |
| text | character string. If includeText is TRUE, the text of all tokens; if it is NA (the default), the text of terminal tokens. If includeText == FALSE, this column is not included. Very long strings (with source of 1000 characters or more) will not be stored; a message giving their length and delimiter will be included instead. |

The rownames of the data frame will be equal to the id values, and the data frame will have a "srcfile" attribute containing the [srcfile](#) record which was used. The rows will be ordered by starting position within the source file, with parent items occurring before their children.

For `getParseText`:

A character vector of the same length as `id` containing the associated text items. If they are not included in `parseData`, they will be retrieved from the original file.

Note

There are a number of differences in the results returned by `getParseData` relative to those in the original **parser** code:

- Fewer columns are kept.
- The internal token number is not returned.
- `col1` starts counting at 1, not 0.
- The id values are not attached to the elements of the parse tree, they are only retained in the table returned by `getParseData`.
- `#line` directives are identified, but other comment markup (e.g., **roxygen** comments) are not.

Parse data by design explore details of the parser implementation, which are subject to change without notice. Applications computing on the parse data may require updates for each R release.

Examples

```
fn <- function(x) {
  x + 1 # A comment, kept as part of the source
}

d <- getParsedData(fn)
if (!is.null(d)) {
  plus <- which(d$token == "'+'")
  sum <- d$parent[plus]
  print(d[as.character(sum),])
  print(getParseText(d, sum))
}
```

getS3method

*Get an S3 Method***Description**

Get a method for an S3 generic, possibly from a namespace or the generic's registry.

Usage

```
getS3method(f, class, optional = FALSE, envir = parent.frame())
```

Arguments

| | |
|-----------------------|-----------------------------------------------------------------------------------------|
| <code>f</code> | a character string giving the name of the generic. |
| <code>class</code> | a character string giving the name of the class. |
| <code>optional</code> | logical: should failure to find the generic or a method be allowed? |
| <code>envir</code> | the environment in which the method and its generic are searched first. |

Details

S3 methods may be hidden in namespaces, and will not then be found by [get](#): this function can retrieve such functions, primarily for debugging purposes.

Further, S3 methods can be registered on the generic when a namespace is loaded, and the registered method will be used if none is visible (using namespace scoping rules).

It is possible that which S3 method will be used may depend on where the generic `f` is called from: `getS3method` returns the method found if `f` were called from the same environment.

Value

The function found, or NULL if no function is found and `optional = TRUE`.

require(stats)
exists("predict.ppr") # false
getS3method("predict", "ppr")
```

| | |
|------------------|-----------------------------|
| getWindowsHandle | <i>Get a Windows Handle</i> |
|------------------|-----------------------------|

Description

Get the Windows handle of a window or of the R process in MS Windows.

Usage

```
getWindowsHandle(which = "Console")
```

Arguments

which a string (see below), or the number of a graphics device window (which must a [windows](#) one).

Details

getWindowsHandle gets the Windows handle. Possible choices for which are:

| | |
|-----------------|----------------------------------------|
| "Console" | The console window handle. |
| "Frame" | The MDI frame window handle. |
| "Process" | The process pseudo-handle. |
| A device number | The window handle of a graphics device |

These values are not normally useful to users, but may be used by developers making addons to R. NULL is returned for the Frame handle if not running in MDI mode, for the Console handle when running Rterm, for any unrecognized string for which, or for a graphics device with no corresponding window.

Other windows (help browsers, etc.) are not accessible through this function.

Value

An external pointer holding the Windows handle, or NULL.

Note

This is only available on Windows.

See Also

[getIdentification](#), [getWindowsHandles](#)

Examples

```
if(.Platform$OS.type == "windows")
  print( getWindowsHandle() )
```

| | |
|-------------------|------------------------------------------------------|
| getWindowsHandles | <i>Get handles of Windows in the MS Windows RGui</i> |
|-------------------|------------------------------------------------------|

Description

This function gets the Windows handles of visible top level windows or windows within the R MDI frame (when using the Rgui).

Usage

```
getWindowsHandles(which = "R", pattern = "", minimized = FALSE)
```

Arguments

| | |
|-----------|----------------------------------------------------------------------------------------|
| which | A vector of strings "R" or "all" (possibly with repetitions). See the Details section. |
| pattern | A vector of patterns that the titles of the windows must match. |
| minimized | A logical vector indicating whether minimized windows should be considered. |

Details

This function will search for Windows handles, for passing to external GUIs or to the [arrangeWindows](#) function. Each of the arguments may be a vector of values. These will be treated as follows:

- The arguments will all be recycled to the same length.
- The corresponding elements of each argument will be applied in separate searches.
- The final result will be the union of the windows identified in each of the searches.

If an element of which is "R", only windows belonging to the current R process will be returned. In MDI mode, those will be the child windows within the R GUI (Rgui) frame. In SDI mode, all windows belonging to the process will be included.

If the element is "all", then top level windows will be returned.

The elements of pattern will be used to make a subset of windows whose title text matches (according to [grep](#)) the pattern.

If minimized = FALSE, minimized windows will be ignored.

Value

A list of external pointers containing the window handles.

Note

This is only available on Windows.

Author(s)

Duncan Murdoch

  getWindowsHandles("all")
})
```

glob2rx

Change Wildcard or Globbing Pattern into Regular Expression

Description

Change *wildcard* aka *globbing* patterns into the corresponding regular expressions ([regex](#)).

Usage

```
glob2rx(pattern, trim.head = FALSE, trim.tail = TRUE)
```

Arguments

| | |
|-----------|-----------------------------------------------------------------------------------------|
| pattern | character vector |
| trim.head | logical specifying if leading " <code>^.*</code> " should be trimmed from the result. |
| trim.tail | logical specifying if trailing " <code>.*\$</code> " should be trimmed from the result. |

Details

This takes a wildcard as used by most shells and returns an equivalent regular expression. '?' is mapped to '.' (match a single character), '*' to '.*' (match any string, including an empty one), and the pattern is anchored (it must start at the beginning and end at the end). Optionally, the resulting regex is simplified.

Note that now even '(', '[' and '{' can be used in pattern, but `glob2rx()` may not work correctly with arbitrary characters in pattern.

Value

A character vector of the same length as the input pattern where each wildcard is translated to the corresponding regular expression.

Author(s)

Martin Maechler, Unix/sed based version, 1991; current: 2004

See Also

[regexp](#) about regular expression, [sub](#), etc about substitutions using regexps.

Examples

```
stopifnot(glob2rx("abc.*") == "^abc\\.\"",
          glob2rx("a?b.*") == "^a.b\\.\"",
          glob2rx("a?b.*", trim.tail = FALSE) == "^a.b\\.\\.*$\"",
          glob2rx("*.doc") == "^.*\\.\\.doc$",
          glob2rx("*.doc", trim.head = TRUE) == "\\\\.doc$",
          glob2rx("*.t*") == "^.*\\.\\.t\"",
          glob2rx("*.t??") == "^.*\\.\\.t..$",
          glob2rx("[*]") == "^.*\\.\\.["
)
```

globalVariables

Declarations Used in Checking a Package

Description

For `globalVariables`, the names supplied are of functions or other objects that should be regarded as defined globally when the check tool is applied to this package. The call to `globalVariables` will be included in the package's source. Repeated calls in the same package accumulate the names of the global variables.

Typical examples are the fields and methods in reference classes, which appear to be global objects to codetools. (This case is handled automatically by `setRefClass()` and friends, using the supplied field and method names.)

For `suppressForeignCheck`, the names supplied are of variables used as `.NAME` in foreign function calls which should not be checked by `checkFF(registration = TRUE)`. Without this declaration, expressions other than simple character strings are assumed to evaluate to registered native symbol objects. The type of call (`.Call`, `.External`, etc.) and argument counts will be checked. With this declaration, checks on those names will usually be suppressed. (If the code uses an expression that should only be evaluated at runtime, the message can be suppressed by wrapping it in a `dontCheck` function call, or by saving it to a local variable, and suppressing messages about that variable. See the example below.)

Usage

```
globalVariables(names, package, add = TRUE)
suppressForeignCheck(names, package, add = TRUE)
```

Arguments

| | |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| names | The character vector of object names. If omitted, the current list of global variables declared in the package will be returned, unchanged. |
| package | The relevant package, usually the character string name of the package but optionally its corresponding namespace environment. When the call to <code>globalVariables</code> or <code>suppressForeignCheck</code> comes in the package's source file, the argument is normally omitted, as in the example below. |
| add | Should the contents of names be added to the current global variables or replace it? |

Details

The lists of declared global variables and native symbol objects are stored in a metadata object in the package's namespace, assuming the `globalVariables` or `suppressForeignCheck` call(s) occur as top-level calls in the package's source code.

The check command, as implemented in package tools, queries the list before checking the R source code in the package for possible problems.

`globalVariables` was introduced in R 2.15.1 and `suppressForeignCheck` was introduced in R 3.1.0 so both should be used conditionally: see the example.

Value

`globalVariables` returns the current list of declared global variables, possibly modified by this call.

`suppressForeignCheck` returns the current list of native symbol objects which are not to be checked.

Note

The global variables list really belongs to a restricted scope (a function or a group of method definitions, for example) rather than the package as a whole. However, implementing finer control would require changes in check and/or in codetools, so in this version the information is stored at the package level.

Author(s)

John Chambers and Duncan Murdoch

See Also

`dontCheck`.

Examples

```
## Not run:  
## assume your package has some code that assigns ".obj1" and ".obj2"  
## but not in a way that codetools can find.  
## In the same source file (to remind you that you did it) add:
```

```

if(getRversion() >= "2.15.1") utils::globalVariables(c(".obj1", ".obj2"))

## To suppress messages about a run-time calculated native symbol,
## save it to a local variable.

## At top level, put this:
if(getRversion() >= "3.1.0") utils::suppressForeignCheck("localvariable")

## Within your function, do the call like this:
localvariable <- if (condition) entry1 else entry2
.Call(localvariable, 1, 2, 3)

## HOWEVER, it is much better practice to write code
## that can be checked thoroughly, e.g.
if(condition) .Call(entry1, 1, 2, 3) else .Call(entry2, 1, 2, 3)

## End(Not run)

```

hashtab

Hash Tables (Experimental)

Description

Create and manipulate mutable hash tables.

Usage

```

hashtab(type = c("identical", "address"), size)
gethash(h, key, nomatch = NULL)
sethash(h, key, value)
remhash(h, key)
numhash(h)
typhash(h)
maphash(h, FUN)
clrhash(h)
is.hashtab(x)
## S3 method for class 'hashtab'
h[[key, nomatch = NULL, ...]]
## S3 replacement method for class 'hashtab'
h[[key, ...]] <- value
## S3 method for class 'hashtab'
print(x, ...)
## S3 method for class 'hashtab'
format(x, ...)
## S3 method for class 'hashtab'
length(x)
## S3 method for class 'hashtab'
str(object, ...)

```

Arguments

| | |
|-----------|-----------------------------------------------------------------------------|
| type | character string specifying the hash table type. |
| size | an integer specifying the expected number of entries. |
| h, object | a hash table. |
| key | an R object to use as a key. |
| nomatch | value to return if key does not match. |
| value | new value to associate with key. |
| FUN | a function of two arguments, the key and the value, to call for each entry. |
| x | object to be tested, printed, or formatted. |
| ... | additional arguments. |

Details

Hash tables are a data structure for efficiently associating keys with values. Hash tables are similar to `environments`, but keys can be arbitrary objects. Like environments, and unlike named lists and most other objects in R, hash tables are mutable, i.e., they are *not* copied when modified and assignment means just giving a new name to the same object.

New hash tables are created by `hashtab`. Two variants are available: keys can be considered to match if they are `identical()` (`type = "identical"`, the default), or if their addresses in memory are equal (`type = "address"`). The default "identical" type is almost always the right choice. The size argument provides a hint for setting the initial hash table size. The hash table will grow if necessary, but specifying an expected size can be more efficient.

`gethash` returns the value associated with key. If key is not present in the table, then the value of `nomatch` is returned.

`sethash` adds a new key/value association or changes the current value for an existing key. `remhash` removes the entry for key, if there is one.

`maphash` calls FUN for each entry in the hash table with two arguments, the entry key and the entry value. The order in which the entries are processed is not predictable. The consequence of FUN adding entries to the table or deleting entries from the table is also not predictable, except that removing the entry currently being processed will have the desired effect.

`clrhash` removes all entries from the hash table.

Value

`hashtab` returns a new hash table of the specified type.

`gethash` returns the value associated with key, or `nomatch` if there is no such value.

`sethash` returns value invisibly.

`remhash` invisibly returns TRUE if an entry for key was found and removed, and FALSE if no entry was found.

`numhash` returns the current number of entries in the table.

`typhash` returns a character string specifying the type of the hash table, one of "identical" or "address".

`maphash` and `clrhash` return NULL invisibly.

Notes

The interface design is based loosely on hash table support in Common Lisp.

The hash function and equality test used for "identical" hash tables are the same as the ones used internally by `duplicated` and `unique`, with two exceptions:

- Closure environments are not ignored when comparing closures. This corresponds to calling `identical()` with `ignore.environment = FALSE`, which is the default for `identical()`.
- External pointer objects are compared as reference objects, corresponding to calling `identical()` with `extptr.as.ref = TRUE`. This ensures that hash tables with keys containing external pointers behave reasonably when serialized and unserialized.

As an experimental feature, the element operator `[[` can also be used get or set hash table entries, and `length` can be used to obtain the number of entries. It is not yet clear whether this is a good idea.

Examples

```
## Create a new empty hash table.
h1 <- hashtab()
h1

## Add some key/value pairs.
sethash(h1, NULL, 1)
sethash(h1, .GlobalEnv, 2)
for (i in seq_along(LETTERS)) sethash(h1, LETTERS[i], i)

## Look up values for some keys.
gethash(h1, NULL)
gethash(h1, .GlobalEnv)
gethash(h1, "Q")

## Remove an entry.
(remhash(h1, NULL))
gethash(h1, NULL)
(remhash(h1, "XYZ"))

## Using the element operator.
h1[["ABC"]]
h1[["ABC", nomatch = 77]]
h1[["ABC"]] <- "DEF"
h1[["ABC"]]

## Integers and real numbers that are equal are considered different
## (not identical) as keys:
identical(3, 3L)
sethash(h1, 3L, "DEF")
gethash(h1, 3L)
gethash(h1, 3)

## Two variables can refer to the same hash table.
h2 <- h1
```

```

identical(h1, h2)
## set in one, see in the "other" <==> really one object with 2 names
sethash(h2, NULL, 77)
gethash(h1, NULL)
str(h1)

## An example of using maphash(): get all hashkeys of a hash table:
hashkeys <- function(h) {
  val <- vector("list", numhash(h))
  idx <- 0
  maphash(h, function(k, v) { idx <- idx + 1
                              val[idx] <- list(k) })
  val
}

kList <- hashkeys(h1)
str(kList) # the *order* is "arbitrary" & cannot be "known"

```

hasName

Check for Name

Description

hasName is a convenient way to test for one or more names in an R object.

Usage

```
hasName(x, name)
```

Arguments

| | |
|------|-------------------------------------------|
| x | Any object. |
| name | One or more character values to look for. |

Details

hasName(x, name) is defined to be equivalent to name %in% names(x), though it will evaluate slightly more quickly. It is intended to replace the common idiom !is.null(x\$name). The latter can be unreliable due to partial name matching; see the example below.

Value

A logical vector of the same length as name containing TRUE if the corresponding entry is in names(x).

See Also

[%in%, exists](#)

Examples

```
x <- list(abc = 1, def = 2)
!is.null(x$abc) # correct
!is.null(x$a)   # this is the wrong test!
hasName(x, "abc")
hasName(x, "a")
```

head

*Return the First or Last Parts of an Object***Description**

Returns the first or last parts of a vector, matrix, table, data frame or function. Since `head()` and `tail()` are generic functions, they may also have been extended to other classes.

Usage

```
head(x, ...)
## Default S3 method:
head(x, n = 6L, ...)
## S3 method for class 'matrix'
head(x, n = 6L, ...) # is exported as head.matrix()
## NB: The methods for 'data.frame' and 'array' are identical to the 'matrix' one

## S3 method for class 'ftable'
head(x, n = 6L, ...)
## S3 method for class 'function'
head(x, n = 6L, ...)

tail(x, ...)
## Default S3 method:
tail(x, n = 6L, keepnums = FALSE, addrownums, ...)
## S3 method for class 'matrix'
tail(x, n = 6L, keepnums = TRUE, addrownums, ...) # exported as tail.matrix()
## NB: The methods for 'data.frame', 'array', and 'table'
##      are identical to the 'matrix' one

## S3 method for class 'ftable'
tail(x, n = 6L, keepnums = FALSE, addrownums, ...)
## S3 method for class 'function'
tail(x, n = 6L, ...)
```

Arguments

x an object

| | |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>n</code> | an integer vector of length up to <code>dim(x)</code> (or 1, for non-dimensioned objects). A logical is silently coerced to integer. Values specify the indices to be selected in the corresponding dimension (or along the length) of the object. A positive value of <code>n[i]</code> includes the first/last <code>n[i]</code> indices in that dimension, while a negative value excludes the last/first <code>abs(n[i])</code> , including all remaining indices. NA or non-specified values (when <code>length(n) < length(dim(x))</code>) select all indices in that dimension. Must contain at least one non-missing value. |
| <code>keepnums</code> | in each dimension, if no names in that dimension are present, create them using the indices included in that dimension. Ignored if <code>dim(x)</code> is NULL or its length 1. |
| <code>addrownums</code> | deprecated - <code>keepnums</code> should be used instead. Taken as the value of <code>keepnums</code> if it is explicitly set when <code>keepnums</code> is not. |
| <code>...</code> | arguments to be passed to or from other methods. |

Details

For vector/array based objects, `head()` (`tail()`) returns a subset of the same dimensionality as `x`, usually of the same class. For historical reasons, by default they select the first (last) 6 indices in the first dimension ("rows") or along the length of a non-dimensioned vector, and the full extent (all indices) in any remaining dimensions. `head.matrix()` and `tail.matrix()` are exported.

The default and array(/matrix) methods for `head()` and `tail()` are quite general. They will work as is for any class which has a `dim()` method, a `length()` method (only required if `dim()` returns NULL), and a `[]` method (that accepts the drop argument and can subset in all dimensions in the dimensioned case).

For functions, the lines of the deparsed function are returned as character strings.

When `x` is an array(/matrix) of dimensionality two and more, `tail()` will add `dimnames` similar to how they would appear in a full printing of `x` for all dimensions `k` where `n[k]` is specified and non-missing and `dimnames(x)[[k]]` (or `dimnames(x)` itself) is NULL. Specifically, the form of the added `dimnames` will vary for different dimensions as follows:

`k=1 (rows):` `"[n,]"` (right justified with whitespace padding)

`k=2 (columns):` `"[,n]"` (with *no* whitespace padding)

`k>2 (higher dims):` `"n"`, i.e., the indices as *character* values

Setting `keepnums = FALSE` suppresses this behaviour.

As `data.frame` subsetting ('indexing') keeps `attributes`, so do the `head()` and `tail()` methods for data frames.

Value

An object (usually) like `x` but generally smaller. Hence, for `arrays`, the result corresponds to `x[, , , drop=FALSE]`. For `fable` objects `x`, a transformed `format(x)`.

Note

For array inputs the output of `tail` when `keepnums` is TRUE, any `dimnames` vectors added for dimensions `>2` are the original numeric indices in that dimension *as character vectors*. This means that,

e.g., for 3-dimensional array `arr`, `tail(arr, c(2,2,-1))[, , 2]` and `tail(arr, c(2,2,-1))[, "2"]` may both be valid but have completely different meanings.

Author(s)

Patrick Burns, improved and corrected by R-Core. Negative argument added by Vincent Goulet. Multi-dimension support added by Gabriel Becker.

Examples

```
head(letters)
head(letters, n = -6L)

head(freeny.x, n = 10L)
head(freeny.y)

head(iris3)
head(iris3, c(6L, 2L))
head(iris3, c(6L, -1L, 2L))

tail(letters)
tail(letters, n = -6L)

tail(freeny.x)
## the bottom-right "corner" :
tail(freeny.x, n = c(4, 2))
tail(freeny.y)

tail(iris3)
tail(iris3, c(6L, 2L))
tail(iris3, c(6L, -1L, 2L))

## iris with dimnames stripped
a3d <- iris3 ; dimnames(a3d) <- NULL
tail(a3d, c(6, -1, 2)) # keepnums = TRUE is default here!
tail(a3d, c(6, -1, 2), keepnums = FALSE)

## data frame w/ a (non-standard) attribute:
treeS <- structure(trees, foo = "bar")
(n <- nrow(treeS))
stopifnot(exprs = { # attribute is kept
  identical(htS <- head(treeS), treeS[1:6, ])
  identical(attr(htS, "foo") , "bar")
  identical(tlS <- tail(treeS), treeS[(n-5):n, ])
  ## BUT if I use "useAttrib(.)", this is *not* ok, when n is of length 2:
  ## --- because [i,j]-indexing of data frames *also* drops "other" attributes ..
  identical(tail(treeS, 3:2), treeS[(n-2):n, 2:3] )
})

tail(library) # last lines of function

head(stats::ftable(Titanic))
```

```
## 1d-array (with named dim) :
a1 <- array(1:7, 7); names(dim(a1)) <- "02"
stopifnot(exprs = {
  identical( tail(a1, 10), a1)
  identical( head(a1, 10), a1)
  identical( head(a1, 1), a1 [1 , drop=FALSE] ) # was a1[1] in R <= 3.6.x
  identical( tail(a1, 2), a1[6:7])
  identical( tail(a1, 1), a1 [7 , drop=FALSE] ) # was a1[7] in R <= 3.6.x
})
```

help

Documentation

Description

help is the primary interface to the help systems.

Usage

```
help(topic, package = NULL, lib.loc = NULL,
      verbose = getOption("verbose"),
      try.all.packages = getOption("help.try.all.packages"),
      help_type = getOption("help_type"))
```

Arguments

| | |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| topic | usually, a name or character string specifying the topic for which help is sought. A character string (enclosed in explicit single or double quotes) is always taken as naming a topic. If the value of topic is a length-one character vector the topic is taken to be the value of the only element. Otherwise topic must be a name or a reserved word (if syntactically valid) or character string. See ‘Details’ for what happens if this is omitted. |
| package | a name or character vector giving the packages to look into for documentation, or NULL. By default, all packages whose namespaces are loaded are used. To avoid a name being deparsed use e.g. (pkg_ref) (see the examples). |
| lib.loc | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries. This is not used for HTML help (see ‘Details’). |
| verbose | logical; if TRUE, the file name is reported. |
| try.all.packages | logical; see Note. |
| help_type | character string: the type of help required. Possible values are "text", "html" and "pdf". Case is ignored, and partial matching is allowed. |

Details

The following types of help are available:

- Plain text help
- HTML help pages with hyperlinks to other topics, shown in a browser by `browseURL`.
(On Unix-alikes, where possible an existing browser window is re-used: the macOS GUI uses its own browser window.)
If for some reason HTML help is unavailable (see `startDynamicHelp`), plain text help will be used instead.
- For help only, typeset as PDF – see the section on ‘Offline help’.

On Unix-alikes: The ‘factory-fresh’ default is text help except from the macOS GUI, which uses HTML help displayed in its own browser window.

On Windows: The default for the type of help is selected when R is installed – the ‘factory-fresh’ default is HTML help.

The rendering of text help will use directional quotes in suitable locales (UTF-8 and single-byte Windows locales): sometimes the fonts used do not support these quotes so this can be turned off by setting `options(useFancyQuotes = FALSE)`.

topic is not optional: if it is omitted R will give

- If a package is specified, (text or, in interactive use only, HTML) information on the package, including hints/links to suitable help topics.
- If `lib.loc` only is specified, a (text) list of available packages.
- Help on help itself if none of the first three arguments is specified.

Some topics need to be quoted (by `backticks`) or given as a character string. These include those which cannot syntactically appear on their own such as unary and binary operators, function and control-flow `reserved` words (including `if`, `else`, `for`, `in`, `repeat`, `while`, `break` and `next`). The other reserved words can be used as if they were names, for example `TRUE`, `NA` and `Inf`.

If multiple help files matching `topic` are found, in interactive use a menu is presented for the user to choose one: in batch use the first on the search path is used. (For HTML help the menu will be an HTML page, otherwise a graphical menu if possible if `getOption("menu.graphics")` is true, the default.)

Note that HTML help does not make use of `lib.loc`: it will always look first in the loaded packages and then along `.libPaths()`.

Offline help

Typeset documentation is produced by running the LaTeX version of the help page through `pdflatex`: this will produce a PDF file.

The appearance of the output can be customized through a file ‘`Rhelp.cfg`’ somewhere in your LaTeX search path: this will be input as a LaTeX style file after `Rd.sty`. Some `environment variables` are consulted, notably `R_PAPERSIZE` (via `getOption("papersize")`) and `R_RD4PDF` (see ‘Making manuals’ in the ‘R Installation and Administration’ manual).

If there is a function `offline_help_helper` in the workspace or further down the search path it is used to do the typesetting, otherwise the function of that name in the `utils` namespace (to which

the first paragraph applies). It should accept at least two arguments, the name of the LaTeX file to be typeset and the type (which is nowadays ignored). It accepts a third argument, `texinputs`, which will give the graphics path when the help document contains figures, and will otherwise not be supplied.

Note

Unless `lib.loc` is specified explicitly, the loaded packages are searched before those in the specified libraries. This ensures that if a library is loaded from a library not in the known library trees, then the help from the loaded library is used. If `lib.loc` is specified explicitly, the loaded packages are *not* searched.

If this search fails and argument `try.all.packages` is `TRUE` and neither packages nor `lib.loc` is specified, then all the packages in the known library trees are searched for help on topic and a list of (any) packages where help may be found is displayed (with hyperlinks for `help_type = "html"`). **NB:** searching all packages can be slow, especially the first time (caching of files by the OS can expedite subsequent searches dramatically).

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

`?` for shortcuts to help topics.

`help.search()` or `??` for finding help pages on a vague topic; `help.start()` which opens the HTML version of the R help pages; `library()` for listing available packages and the help objects they contain; `data()` for listing available data sets; `methods()`.

Use `prompt()` to get a prototype for writing help pages of your own package.

Examples

```
help()
help(help)           # the same

help(lapply)

help("for")          # or ?"for", but quotes/backticks are needed

try({# requires working TeX installation:
  help(dgamma, help_type = "pdf")
  ## -> nicely formatted pdf -- including math formula -- for help(dgamma):
  system2(getOption("pdfviewer"), "dgamma.pdf", wait = FALSE)
})

help(package = "splines") # get help even when package is not loaded

topi <- "women"
help(topi)
```

```
try(help("bs", try.all.packages = FALSE)) # reports not found (an error)
help("bs", try.all.packages = TRUE)      # reports can be found
                                         # in package 'splines'

## For programmatic use:
topic <- "family"; pkg_ref <- "stats"
help((topic), (pkg_ref))
```

help.request

Send a Post to R-help

Description

Prompts the user to check they have done all that is expected of them before sending a post to the R-help mailing list, provides a template for the post with session information included and optionally sends the email (on Unix systems).

Usage

```
help.request(subject = "",
             address = "r-help@R-project.org",
             file = "R.help.request", ...)
```

Arguments

| | |
|---------|-----------------------------------------------------------------------------------------------------------------------------|
| subject | subject of the email. Please do not use single quotes (') in the subject! Post separate help requests for multiple queries. |
| address | recipient's email address. |
| file | filename to use (if needed) for setting up the email. |
| ... | additional named arguments such as method and ccaddress to pass to create.post . |

Details

This function is not intended to replace the posting guide. Please read the guide before posting to R-help or using this function (see <https://www.r-project.org/posting-guide.html>).

The `help.request` function:

- asks whether the user has consulted relevant resources, stopping and opening the relevant URL if a negative response is given.
- checks whether the current version of R is being used and whether the add-on packages are up-to-date, giving the option of updating where necessary.
- asks whether the user has prepared appropriate (minimal, reproducible, self-contained, commented) example code ready to paste into the post.

Once this checklist has been completed a template post is prepared including current session information, and passed to [create.post](#).

Value

Nothing useful.

Author(s)

Heather Turner, based on the then current code and help page of [bug.report\(\)](#).

See Also

The posting guide (<https://www.r-project.org/posting-guide.html>), also [sessionInfo\(\)](#) from which you may add to the help request.

[create.post](#).

help.search

Search the Help System

Description

Allows for searching the help system for documentation matching a given character string in the (file) name, alias, title, concept or keyword entries (or any combination thereof), using either [fuzzy matching](#) or [regular expression](#) matching. Names and titles of the matched help entries are displayed nicely formatted.

Vignette names, titles and keywords and demo names and titles may also be searched.

Usage

```
help.search(pattern, fields = c("alias", "concept", "title"),
            apropos, keyword, whatis, ignore.case = TRUE,
            package = NULL, lib.loc = NULL,
            help.db = getOption("help.db"),
            verbose = getOption("verbose"),
            rebuild = FALSE, agrep = NULL, use_UTF8 = FALSE,
            types = getOption("help.search.types"))
??pattern
field??pattern
```

Arguments

| | |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pattern | a character string to be matched in the specified fields. If this is given, the arguments apropos, keyword, and whatis are ignored. |
| fields | a character vector specifying the fields of the help database to be searched. The entries must be abbreviations of "name", "title", "alias", "concept", and "keyword", corresponding to the help page's (file) name, its title, the topics and concepts it provides documentation for, and the keywords it can be classified to. See below for details and how vignettes and demos are searched. |
| apropos | a character string to be matched in the help page topics and title. |

| | |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| keyword | a character string to be matched in the help page ‘keywords’. ‘Keywords’ are really categories: the standard categories are listed in file ‘R.home("doc")/KEYWORDS’ (see also the example) and some package writers have defined their own. If keyword is specified, agrep defaults to FALSE. |
| whatis | a character string to be matched in the help page topics. |
| ignore.case | a logical. If TRUE, case is ignored during matching; if FALSE, pattern matching is case sensitive. |
| package | a character vector with the names of packages to search through, or NULL in which case <i>all</i> available packages in the library trees specified by lib.loc are searched. |
| lib.loc | a character vector describing the location of R library trees to search through, or NULL. The default value of NULL corresponds to all libraries currently known. |
| help.db | a character string giving the file path to a previously built and saved help database, or NULL. |
| verbose | logical; if TRUE, the search process is traced. Integer values are also accepted, with TRUE being equivalent to 2, and 1 being less verbose. On Windows a progress bar is shown during rebuilding, and on Unix a heartbeat is shown for verbose = 1 and a package-by-package list for verbose >= 2. |
| rebuild | a logical indicating whether the help database should be rebuilt. This will be done automatically if lib.loc or the search path is changed, or if package is used and a value is not found. |
| agrep | if NULL (the default unless keyword is used) and the character string to be matched consists of alphanumeric characters, whitespace or a dash only, approximate (fuzzy) matching via agrep is used unless the string has fewer than 5 characters; otherwise, it is taken to contain a regular expression to be matched via grep . If FALSE, approximate matching is not used. Otherwise, one can give a numeric or a list specifying the maximal distance for the approximate match, see argument max.distance in the documentation for agrep . |
| use_UTF8 | logical: should results be given in UTF-8 encoding? Also changes the meaning of regexps in agrep to be Perl regexps. |
| types | a character vector listing the types of documentation to search. The entries must be abbreviations of "vignette" "help" or "demo". Results will be presented in the order specified. |
| field | a single value of fields to search. |

Details

Upon installation of a package, a pre-built help.search index is serialized as ‘hsearch.rds’ in the ‘Meta’ directory (provided the package has any help pages). Vignettes are also indexed in the ‘Meta/vignette.rds’ file. These files are used to create the help search database via [hsearch_db](#).

The arguments `apropos` and `whatis` play a role similar to the Unix commands with the same names.

Searching with `agrep = FALSE` will be several times faster than the default (once the database is built). However, approximate searches should be fast enough (around a second with 5000 packages installed).

If possible, the help database is saved in memory for use by subsequent calls in the session.

Note that currently the aliases in the matching help files are not displayed.

As with `?`, in `??` the pattern may be prefixed with a package name followed by `::` or `:::` to limit the search to that package.

For help files, ‘keyword’ entries which are not among the standard keywords as listed in file ‘KEYWORDS’ in the R documentation directory are taken as concepts. For standard keyword entries different from ‘internal’, the corresponding descriptions from file ‘KEYWORDS’ are additionally taken as concepts. All ‘\concept’ entries used as concepts.

Vignettes are searched as follows. The “name” and “alias” are both the base of the vignette filename, and the “concept” entries are taken from the ‘\VignetteKeyword’ entries. Vignettes are not classified using the help system “keyword” classifications. Demos are handled similarly to vignettes, without the “concept” search.

Value

The results are returned in a list object of class “hsearch”, which has a print method for nicely formatting the results of the query. This mechanism is experimental, and may change in future versions of R.

In R.app on macOS, this will show up a browser with selectable items. On exiting this browser, the help pages for the selected items will be shown in separate help windows.

The internal format of the class is undocumented and subject to change.

See Also

[hsearch_db](#) for more information on the help search database employed, and for utilities to inspect available concepts and keywords.

[help](#); [help.start](#) for starting the hypertext (currently HTML) version of R’s online documentation, which offers a similar search mechanism.

[RSiteSearch](#) to access an on-line search of R resources.

[apropos](#) uses regexps and has nice examples.

Examples

```
help.search("linear models")    # In case you forgot how to fit linear
                                # models
help.search("non-existent topic")

??utils::help # All the topics matching "help" in the utils package

## Documentation with topic/concept/title matching 'print'
## (disabling fuzzy matching to not also match 'point')
help.search("print", agrep = FALSE)
help.search(apropos = "print", agrep = FALSE) # ignores concepts

## Help pages with documented topics starting with 'try':
help.search("^try", fields = "alias")
alias??"^try" # the same
```

```
## Help pages documenting high-level plots:
help.search(keyword = "hplot")

RShowDoc("KEYWORDS") # show all keywords
```

| | |
|------------|--------------------------------|
| help.start | <i>Hypertext Documentation</i> |
|------------|--------------------------------|

Description

Start the hypertext (currently HTML) version of R's online documentation.

Usage

```
help.start(update = FALSE, gui = "irrelevant",
           browser = getOption("browser"), remote = NULL)
```

Arguments

| | |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| update | logical: should this attempt to update the package index to reflect the currently available packages. (Not attempted if remote is non-NULL.) |
| gui | just for compatibility with S-PLUS. |
| browser | the name of the program to be used as hypertext browser. It should be in the PATH, or a full path specified. Alternatively, it can be an R function which will be called with a URL as its only argument. This option is normally unset on Windows, when the file-association mechanism will be used. |
| remote | A character string giving a valid URL for the ' <i>R_HOME</i> ' directory on a remote location. |

Details

Unless remote is specified this requires the HTTP server to be available (it will be started if possible: see [startDynamicHelp](#)).

One of the links on the index page is the HTML package index, '*R_DOC_DIR/html/packages.html*', which can be remade by [make.packages.html\(\)](#). For local operation, the HTTP server will remake a temporary version of this list when the link is first clicked, and each time thereafter check if updating is needed (if [.libPaths](#) has changed or any of the directories has been changed). This can be slow, and using update = TRUE will ensure that the packages list is updated before launching the index page.

Argument remote can be used to point to HTML help published by another R installation: it will typically only show packages from the main library of that installation.

See Also

[help\(\)](#) for on- and off-line help in other formats.
[browseURL](#) for how the help file is displayed.
[RSiteSearch](#) to access an on-line search of R resources.

Examples

```
help.start()

## the 'remote' arg can be tested by
help.start(remote = paste0("file://", R.home()))
```

hsearch-utils

Help Search Utilities

Description

Utilities for searching the help system.

Usage

```
hsearch_db(package = NULL, lib.loc = NULL,
            types = getOption("help.search.types"),
            verbose = getOption("verbose"),
            rebuild = FALSE, use_UTF8 = FALSE)
hsearch_db_concepts(db = hsearch_db())
hsearch_db_keywords(db = hsearch_db())
```

Arguments

| | |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| package | a character vector with the names of packages to search through, or NULL in which case <i>all</i> available packages in the library trees specified by <code>lib.loc</code> are searched. |
| lib.loc | a character vector describing the location of R library trees to search through, or NULL. The default value of NULL corresponds to all libraries currently known. |
| types | a character vector listing the types of documentation to search. See help.search for details. |
| verbose | a logical controlling the verbosity of building the help search database. See help.search for details. |
| rebuild | a logical indicating whether the help search database should be rebuilt. See help.search for details. |
| use_UTF8 | logical: should results be given in UTF-8 encoding? |
| db | a help search database as obtained by calls to <code>hsearch_db()</code> . |

Details

`hsearch_db()` builds and caches the help search database for subsequent use by [help.search](#). (In fact, re-builds only when forced (`rebuild = TRUE`) or “necessary”.)

The format of the help search database is still experimental, and may change in future versions. Currently, it consists of four tables: one with base information about all documentation objects found, including their names and titles and unique ids; three more tables contain the individual

aliases, concepts and keywords together with the ids of the documentation objects they belong to. Separating out the latter three tables accounts for the fact that a single documentation object may provide several of these entries, and allows for efficient searching.

See the details in [help.search](#) for how searchable entries are interpreted according to help type.

`hsearch_db_concepts()` and `hsearch_db_keywords()` extract all concepts or keywords, respectively, from a help search database, and return these in a data frame together with their total frequencies and the numbers of packages they are used in, with entries sorted in decreasing total frequency.

Examples

```
db <- hsearch_db()
## Total numbers of documentation objects, aliases, keywords and
## concepts (using the current format):
sapply(db, NROW)
## Can also be obtained from print method:
db
## 10 most frequent concepts:
head(hsearch_db_concepts(), 10)
## 10 most frequent keywords:
head(hsearch_db_keywords(), 10)
```

INSTALL

Install Add-on Packages

Description

Utility for installing add-on packages.

Usage

```
R CMD INSTALL [options] [-l lib] pkgs
```

Arguments

| | |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pkgs</code> | a space-separated list with the path names of the packages to be installed. See ‘Details’. |
| <code>lib</code> | the path name of the R library tree to install to. Also accepted in the form ‘--library=lib’. Paths including spaces should be quoted, using the conventions for the shell in use. |
| <code>options</code> | a space-separated list of options through which in particular the process for building the help files can be controlled. Use <code>R CMD INSTALL --help</code> for the full current list of options. |

Details

This will stop at the first error, so if you want all the pkgs to be tried, call this via a shell loop.

If used as R CMD INSTALL pkgs without explicitly specifying lib, packages are installed into the library tree rooted at the first directory in the library path which would be used by R run in the current environment.

To install into the library tree *lib*, use R CMD INSTALL -l *lib* *pkgs*. This prepends lib to the library path for duration of the install, so required packages in the installation directory will be found (and used in preference to those in other libraries).

Both lib and the elements of pkgs may be absolute or relative path names of directories. pkgs may also contain names of package archive files: these are then extracted to a temporary directory. These are tarballs containing a single directory, optionally compressed by gzip, bzip2, xz or compress. Finally, binary package archive files (as created by R CMD INSTALL --build) can be supplied.

Tarballs are by default unpackaged by the internal `untar` function: if needed an external tar command can be specified by the environment variable R_INSTALL_TAR: please ensure that it can handle the type of compression used on the tarball. (This is sometimes needed for tarballs containing invalid or unsupported sections, and can be faster on very large tarballs. Setting R_INSTALL_TAR to 'tar.exe' has been needed to overcome permissions issues on some Windows systems.)

The package sources can be cleaned up prior to installation by '--preclean' or after by '--clean': cleaning is essential if the sources are to be used with more than one architecture or platform.

Some package sources contain a 'configure' script that can be passed arguments or variables via the option '--configure-args' and '--configure-vars', respectively, if necessary. The latter is useful in particular if libraries or header files needed for the package are in non-system directories. In this case, one can use the configure variables LIBS and CPPFLAGS to specify these locations (and set these via '--configure-vars'), see section 'Configuration variables' in 'R Installation and Administration' for more information. (If these are used more than once on the command line they are concatenated.) The configure mechanism can be bypassed using the option '--no-configure'.

If the attempt to install the package fails, leftovers are removed. If the package was already installed, the old version is restored. This happens either if a command encounters an error or if the install is interrupted from the keyboard: after cleaning up the script terminates.

For details of the locking which is done, see the section 'Locking' in the help for [install.packages](#).

Option '--build' can be used to tar up the installed package for distribution as a binary package (as used on macOS). This is done by `utils::tar` unless environment variable R_INSTALL_TAR is set.

By default a package is installed with static HTML help pages if and only if R was: use options '--html' and '--no-html' to override this.

Packages are not by default installed keeping the source formatting (see the `keep.source` argument to [source](#)): this can be enabled by the option '--with-keep.source' or by setting environment variable R_KEEP_PKG_SOURCE to yes.

Specifying the '--install-tests' option copies the contents of the 'tests' directory into the package installation. If the R_ALWAYS_INSTALL_TESTS environment variable is set to a true value, the tests will be installed even if '--install-tests' is omitted.

Use R CMD INSTALL --help for concise usage information, including all the available options.

Sub-architectures

An R installation can support more than one sub-architecture: currently this is most commonly used for 32- and 64-bit builds on Windows.

For such installations, the default behaviour is to try to install source packages for all installed sub-architectures unless the package has a configure script or a 'src/Makefile' (or 'src/Makefile.win' on Windows), when only compiled code for the sub-architecture running R CMD INSTALL is installed.

To install a source package with compiled code only for the sub-architecture used by R CMD INSTALL, use '--no-multiarch'. To install just the compiled code for another sub-architecture, use '--libs-only'.

There are two ways to install for all available sub-architectures. If the configure script is known to work for both Windows architectures, use flag '--force-biarch' (and packages can specify this *via* a 'Biarch: yes' field in their DESCRIPTION files). Second, a single tarball can be installed with

```
R CMD INSTALL --merge-multiarch mypkg_version.tar.gz
```

Staged installation

The default way to install source packages changed in R 3.6.0, so packages are first installed to a temporary location and then (if successful) moved to the destination library directory. Some older packages were written in ways that assume direct installation to the destination library.

Staged installation can currently be overridden by having a line 'StagedInstall: no' in the package's 'DESCRIPTION' file, *via* flag '--no-staged-install' or by setting environment variable R_INSTALL_STAGED to a false value (e.g. 'false' or 'no').

Staged installation requires either '--pkglock' or '--lock', one of which is used by default.

Note

The options do not have to precede 'pkgs' on the command line, although it will be more legible if they do. All the options are processed before any packages, and where options have conflicting effects the last one will win.

Some parts of the operation of INSTALL depend on the R temporary directory (see [tempdir](#), usually under '/tmp') having both write and execution access to the account running R. This is usually the case, but if '/tmp' has been mounted as noexec, environment variable TMPDIR may need to be set to a directory from which execution is allowed.

install.packages

*Install Packages from Repositories or Local Files***Description**

Download and install packages from CRAN-like repositories or from local files.

Usage

```
install.packages(pkgs, lib, repos = getOption("repos"),
  contriburl = contrib.url(repos, type),
  method, available = NULL, destdir = NULL,
  dependencies = NA, type = getOption("pkgType"),
  configure.args = getOption("configure.args"),
  configure.vars = getOption("configure.vars"),
  clean = FALSE, Ncpus = getOption("Ncpus", 1L),
  verbose = getOption("verbose"),
  libs_only = FALSE, INSTALL_opts, quiet = FALSE,
  keep_outputs = FALSE, ...)
```

Arguments

- | | |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pkgs | <p>character vector of the names of packages whose current versions should be downloaded from the repositories.</p> <p>If repos = NULL, a character vector of file paths,</p> <p>on Windows, file paths of ‘.zip’ files containing binary builds of packages. (‘http://’ and ‘file://’ URLs are also accepted and the files will be downloaded and installed from local copies.) Source directories or file paths or URLs of archives may be specified with type = “source”, but some packages need suitable tools installed (see the ‘Details’ section).</p> <p>On Unix-alikes, these file paths can be source directories or archives or binary package archive files (as created by R CMD build --binary). (‘http://’ and ‘file://’ URLs are also accepted and the files will be downloaded and installed from local copies.) On a CRAN build of R for macOS these can be ‘.tgz’ files containing binary package archives. Tilde-expansion will be done on file paths.</p> <p>If this is missing, a listbox of available packages is presented where possible in an interactive R session.</p> |
| lib | <p>character vector giving the library directories where to install the packages. Recycled as needed. If missing, defaults to the first element of <code>.libPaths()</code>.</p> |
| repos | <p>character vector, the base URL(s) of the repositories to use, e.g., the URL of a CRAN mirror such as “https://cloud.r-project.org”. For more details on supported URL schemes see url.</p> <p>Can be NULL to install from local files, directories or URLs: this will be inferred by extension from pkgs if of length one.</p> |

| | |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| contriburl | URL(s) of the contrib sections of the repositories. Use this argument if your repository mirror is incomplete, e.g., because you mirrored only the ‘contrib’ section, or only have binary packages. Overrides argument repos. Incompatible with type = “both”. |
| method | download method, see download.file . Unused if a non-NULL available is supplied. |
| available | a matrix as returned by available.packages listing packages available at the repositories, or NULL when the function makes an internal call to available.packages. Incompatible with type = “both”. |
| destdir | directory where downloaded packages are stored. If it is NULL (the default) a subdirectory downloaded_packages of the session temporary directory will be used (and the files will be deleted at the end of the session). |
| dependencies | <p>logical indicating whether to also install uninstalled packages which these packages depend on/link to/import/suggest (and so on recursively). Not used if repos = NULL. Can also be a character vector, a subset of c(“Depends”, “Imports”, “LinkingTo”, “Suggests”, “Enhances”).</p> <p>Only supported if lib is of length one (or missing), so it is unambiguous where to install the dependent packages. If this is not the case it is ignored, with a warning.</p> <p>The default, NA, means c(“Depends”, “Imports”, “LinkingTo”).</p> <p>TRUE means to use c(“Depends”, “Imports”, “LinkingTo”, “Suggests”) for pkgs and c(“Depends”, “Imports”, “LinkingTo”) for added dependencies: this installs all the packages needed to run pkgs, their examples, tests and vignettes (if the package author specified them correctly).</p> <p>In all of these, “LinkingTo” is omitted for binary packages.</p> |
| type | character, indicating the type of package to download and install. Will be “source” except on Windows and some macOS builds: see the section on ‘Binary packages’ for those. |
| configure.args | <p>(Used only for source installs.) A character vector or a named list. If a character vector with no names is supplied, the elements are concatenated into a single string (separated by a space) and used as the value for the ‘--configure-args’ flag in the call to R CMD INSTALL. If the character vector has names these are assumed to identify values for ‘--configure-args’ for individual packages. This allows one to specify settings for an entire collection of packages which will be used if any of those packages are to be installed. (These settings can therefore be re-used and act as default settings.)</p> <p>A named list can be used also to the same effect, and that allows multi-element character strings for each package which are concatenated to a single string to be used as the value for ‘--configure-args’.</p> |
| configure.vars | (Used only for source installs.) Analogous to configure.args for flag ‘--configure-vars’, which is used to set environment variables for the configure run. |
| clean | a logical value indicating whether to add the ‘--clean’ flag to the call to R CMD INSTALL. This is sometimes used to perform additional operations at the end of the package installation in addition to removing intermediate files. |

| | |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Ncpus | the number of parallel processes to use for a parallel install of more than one source package. Values greater than one are supported if the make command specified by <code>Sys.getenv("MAKE", "make")</code> accepts argument <code>'-k -j <Ncpus>'</code> . |
| verbose | a logical indicating if some “progress report” should be given. |
| libs_only | a logical value: should the <code>'--libs-only'</code> option be used to install only additional sub-architectures for source installs? (See also <code>INSTALL_opts</code> .) This can also be used on Windows to install just the DLL(s) from a binary package, e.g. to add 64-bit DLLs to a 32-bit install. |
| INSTALL_opts | an optional character vector of additional option(s) to be passed to R CMD INSTALL for a source package install. E.g., <code>c("--html", "--no-multiarch", "--no-test-load")</code> . Can also be a named list of character vectors to be used as additional options, with names the respective package names. |
| quiet | logical: if true, reduce the amount of output. This is <i>not</i> passed to <code>available.packages()</code> in case that is called, on purpose. |
| keep_outputs | a logical: if true, keep the outputs from installing source packages in the current working directory, with the names of the output files the package names with <code>' .out'</code> appended (overwriting existing files, possibly from previous installation attempts). Alternatively, a character string giving the directory in which to save the outputs. Ignored when installing from local files. |
| ... | further arguments to be passed to <code>download.file</code> , <code>available.packages</code> , or to the functions for binary installs on macOS and Windows (which accept an argument <code>"lock"</code> : see the section on ‘Locking’). |

Details

This is the main function to install packages. It takes a vector of names and a destination library, downloads the packages from the repositories and installs them. (If the library is omitted it defaults to the first directory in `.libPaths()`, with a message if there is more than one.) If `lib` is omitted or is of length one and is not a (group) writable directory, in interactive use the code offers to create a personal library tree (the first element of `Sys.getenv("R_LIBS_USER")`) and install there.

Detection of a writable directory is problematic on Windows: see the ‘Note’ section.

For installs from a repository an attempt is made to install the packages in an order that respects their dependencies. This does assume that all the entries in `lib` are on the default library path for installs (set by environment variable `R_LIBS`).

You are advised to run `update.packages` before `install.packages` to ensure that any already installed dependencies have their latest versions.

Value

Invisible NULL.

Binary packages

This section applies only to platforms where binary packages are available: Windows and CRAN builds for macOS.

R packages are primarily distributed as *source* packages, but *binary* packages (a packaging up of the installed package) are also supported, and the type most commonly used on Windows and by the CRAN builds for macOS. This function can install either type, either by downloading a file from a repository or from a local file.

Possible values of type are (currently) "source", "mac.binary", and "win.binary": the appropriate binary type where supported can also be selected as "binary".

For a binary install from a repository, the function checks for the availability of a source package on the same repository, and reports if the source package has a later version, or is available but no binary version is. This check can be suppressed by using

```
options(install.packages.check.source = "no")
```

and should be if there is a partial repository containing only binary files.

An alternative (and the current default) is "both" which means 'use binary if available and current, otherwise try source'. The action if there are source packages which are preferred but may contain code which needs to be compiled is controlled by `getOption("install.packages.compile.from.source")`. `type = "both"` will be silently changed to "binary" if either `contriburl` or `available` is specified.

Using packages with `type = "source"` always works provided the package contains no C/C++/Fortran code that needs compilation. Otherwise,

on Windows, you will need to have installed the Rtools collection as described in the 'R for Windows FAQ' and you must have the PATH environment variable set up as required by Rtools.

For a 32/64-bit installation of R on Windows, a small minority of packages with compiled code need either `INSTALL_opts = "--force-biarch"` or `INSTALL_opts = "--merge-multiarch"` for a source installation. (It is safe to always set the latter when installing from a repository or tarballs, although it will be a little slower.)

When installing a package on Windows, `install.packages` will abort the install if it detects that the package is already installed and is currently in use. In some circumstances (e.g., multiple instances of R running at the same time and sharing a library) it will not detect a problem, but the installation may fail as Windows locks files in use.

On Unix-alikes, when the package contains C/C++/Fortran code that needs compilation, suitable compilers and related tools need to be installed. On macOS you need to have installed the 'Command-line tools for Xcode' (see the 'R Installation and Administration' manual) and if needed by the package a Fortran compiler, and have them in your path.

Locking

There are various options for locking: these differ between source and binary installs.

By default for a source install, the library directory is 'locked' by creating a directory '`00LOCK`' within it. This has two purposes: it prevents any other process installing into that library concurrently, and is used to store any previous version of the package to restore on error. A finer-grained locking is provided by the option '`--pkglock`' which creates a separate lock for each package: this allows enough freedom for parallel installation. Per-package locking is the default when installing a single package, and for multiple packages when `Ncpus > 1L`. Finally locking (and restoration on error) can be suppressed by '`--no-lock`'.

For a macOS binary install, no locking is done by default. Setting argument `lock` to `TRUE` (it defaults to the value of `getOption("install.lock", FALSE)`) will use per-directory locking as described for source installs. For Windows binary install, per-directory locking is used by default (`lock` defaults to the value of `getOption("install.lock", TRUE)`). If the value is `"pkglock"` per-package locking will be used.

If package locking is used on Windows with `libs_only = TRUE` and the installation fails, the package will be restored to its previous state.

Note that it is possible for the package installation to fail so badly that the lock directory is not removed: this inhibits any further installs to the library directory (or for `'--pkglock'`, of the package) until the lock directory is removed manually.

Parallel installs

Parallel installs are attempted if `pkgs` has length greater than one and `Ncpus > 1`. It makes use of a parallel make, so the make specified (default make) when R was built must be capable of supporting `make -j N`: GNU make, dmake and pmake do, but Solaris make and older FreeBSD make do not: if necessary environment variable `MAKE` can be set for the current session to select a suitable make.

`install.packages` needs to be able to compute all the dependencies of `pkgs` from available, including if one element of `pkgs` depends indirectly on another. This means that if for example you are installing CRAN packages which depend on Bioconductor packages which in turn depend on CRAN packages, available needs to cover both CRAN and Bioconductor packages.

Timeouts

A limit on the elapsed time for each call to R CMD INSTALL (so for source installs) can be set *via* environment variable `_R_INSTALL_PACKAGES_ELAPSED_TIMEOUT_`: in seconds (or in minutes or hours with optional suffix `'m'` or `'h'`, suffix `'s'` being allowed for the default seconds) with `0` meaning no limit.

For non-parallel installs this is implemented *via* the `timeout` argument of `system2`: for parallel installs *via* the OS's `timeout` command. (The one tested is from GNU **coreutils**, commonly available on Linux but not other Unix-alikes. If no such command is available the timeout request is ignored, with a warning. On Windows, one needs to specify a suitable `timeout` command via environment variable `R_TIMEOUT`, because `'c:/Windows/system32/timeout.exe'` is not.) For parallel installs a `'Error 124'` message from make indicates that timeout occurred.

Timeouts during installation might leave lock directories behind and not restore previous versions.

Version requirements on source installs

If you are not running an up-to-date version of R you may see a message like

```
package 'RODBC' is not available (for R version 3.5.3)
```

One possibility is that the package is not available in any of the selected repositories; another is that it is available but only for current or recent versions of R. For CRAN packages take a look at the package's CRAN page (e.g., <https://cran.r-project.org/package=RODBC>). If that indicates in the `'Depends'` field a dependence on a later version of R you will need to look in the `'Old sources'` section and select the URL of a version of comparable age to your R. Then you can supply that

URL as the first argument of `install.packages()`: you may need to first manually install its dependencies.

For other repositories, using `available.packages(filters = "OS_type")[pkghname,]` will show if the package is available for any R version (for your OS).

Note

On Unix-alikes: Some binary distributions of R have INSTALL in a separate bundle, e.g. an R-devel RPM. `install.packages` will give an error if called with `type = "source"` on such a system.

Some binary Linux distributions of R can be installed on a machine without the tools needed to install packages: a possible remedy is to do a complete install of R which should bring in all those tools as dependencies.

On Windows: `install.packages` tries to detect if you have write permission on the library directories specified, but Windows reports unreliably. If there is only one library directory (the default), R tries to find out by creating a test directory, but even this need not be the whole story: you may have permission to write in a library directory but lack permission to write binary files (such as `.dll` files) there. See the 'R for Windows FAQ' for workarounds.

Examples

```
## Not run:
## A Linux example for Fedora's layout of udunits2 headers.
install.packages(c("ncdf4", "RNetCDF"),
  configure.args = c(RNetCDF = "--with-netcdf-include=/usr/include/udunits2"))

## End(Not run)
```

| | |
|---------------------------------|--------------------------------|
| <code>installed.packages</code> | <i>Find Installed Packages</i> |
|---------------------------------|--------------------------------|

Description

Find (or retrieve) details of all packages installed in the specified libraries.

Usage

```
installed.packages(lib.loc = NULL, priority = NULL,
                  noCache = FALSE, fields = NULL,
                  subarch = .Platform$r_arch, ...)
```

Arguments

| | |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>lib.loc</code> | character vector describing the location of R library trees to search through, or NULL for all known trees (see .libPaths). |
| <code>priority</code> | character vector or NULL (default). If non-null, used to select packages; "high" is equivalent to <code>c("base", "recommended")</code> . To select all packages without an assigned priority use <code>priority = NA_character_</code> . |
| <code>noCache</code> | Do not use cached information, nor cache it. |
| <code>fields</code> | a character vector giving the fields to extract from each package's 'DESCRIPTION' file in addition to the default ones, or NULL (default). Unavailable fields result in NA values. |
| <code>subarch</code> | character string or NULL. If non-null and non-empty, used to select packages which are installed for that sub-architecture. |
| <code>...</code> | allows unused arguments to be passed down from other functions. |

Details

`installed.packages` scans the 'DESCRIPTION' files of each package found along `lib.loc` and returns a matrix of package names, library paths and version numbers.

The information found is cached (by library) for the R session and specified `fields` argument, and updated only if the top-level library directory has been altered, for example by installing or removing a package. If the cached information becomes confused, it can be avoided by specifying `noCache = TRUE`.

Value

A matrix with one row per package, row names the package names and column names (currently) "Package", "LibPath", "Version", "Priority", "Depends", "Imports", "LinkingTo", "Suggests", "Enhances", "OS_type", "License" and "Built" (the R version the package was built under). Additional columns can be specified using the `fields` argument.

Note

This needs to read several files per installed package, which will be slow on Windows and on some network-mounted file systems.

It will be slow when thousands of packages are installed, so do not use it to find out if a named package is installed (use [find.package](#) or [system.file](#)) nor to find out if a package is usable (call [requireNamespace](#) or [require](#) and check the return value) nor to find details of a small number of packages (use [packageDescription](#)).

See Also

[update.packages](#), [install.packages](#), [INSTALL](#), [REMOVE](#).

Examples

```
## confine search to .Library for speed
str(ip <- installed.packages(.Library, priority = "high"))
ip[, c(1,3:5)]
plic <- installed.packages(.Library, priority = "high", fields = "License")
## what licenses are there:
table( plic[, "License"] )

## Recommended setup (by many pros):
## Keep packages that come with R (priority="high") and all others separate!
## Consequently, .Library, R's "system" library, shouldn't have any
## non-"high"-priority packages :
pSys <- installed.packages(.Library, priority = NA_character_)
length(pSys) == 0 # TRUE under such a setup
```

isS3method

Is 'method' the Name of an S3 Method?

Description

Checks if method is the name of a valid / registered S3 method. Alternatively, when f and class are specified, it is checked if f is the name of an S3 generic function and `paste(f, class, sep=".")` is a valid S3 method.

Usage

```
isS3method(method, f, class, envir = parent.frame())
```

Arguments

| | |
|--------|-------------------------------------------------------------------------------------------------------------------------------|
| method | a character string, typically of the form " <i>fn.class</i> ". If omitted, f and class have to be specified instead. |
| f | optional character string, typically specifying an S3 generic function. Used, when method is not specified. |
| class | optional character string, typically specifying an S3 class name. Used, when method is not specified. |
| envir | the environment in which the method and its generic are searched first, as in getS3method() . |

Value

[logical](#) TRUE or FALSE

See Also

[methods](#), [getS3method](#).

Examples

```

isS3method("t")          # FALSE - it is an S3 generic
isS3method("t.default")  # TRUE
isS3method("t.ts")       # TRUE
isS3method("t.test")     # FALSE
isS3method("t.data.frame")# TRUE
isS3method("t.lm")       # FALSE - not existing
isS3method("t.foo.bar")  # FALSE - not existing

## S3 methods with "4 parts" in their name:
ff <- c("as.list", "as.matrix", "is.na", "row.names", "row.names<-")
for(m in ff) if(isS3method(m)) stop("wrongly declared an S3 method: ", m)
(m4 <- paste(ff, "data.frame", sep="."))
for(m in m4) if(!isS3method(m)) stop("not an S3 method: ", m)

```

isS3stdGeneric

Check if a Function Acts as an S3 Generic

Description

Determines whether `f` acts as a standard S3-style generic function.

Usage

```
isS3stdGeneric(f)
```

Arguments

`f` a function object

Details

A closure is considered a standard S3 generic if the first expression in its body calls [UseMethod](#). Functions which perform operations before calling `UseMethod` will not be considered “standard” S3 generics.

If `f` is currently being traced, i.e., inheriting from class “traceable”, the definition of the original untraced version of the function is used instead.

Value

If `f` is an S3 generic, a logical containing TRUE with the name of the S3 generic (the string passed to `UseMethod`). Otherwise, FALSE (unnamed).

Description

Front-end for creating executable programs on unix-alikes, i.e., not on Windows.

Usage

R CMD LINK [options] linkcmd

Arguments

| | |
|---------|-----------------------------------------------------------------------------------------------------------------------|
| linkcmd | a list of commands to link together suitable object files (include library objects) to create the executable program. |
| options | further options to control the linking, or for obtaining information about usage and version. |

Details

The linker front-end is useful in particular when linking against the R shared or static library: see the examples.

The actual linking command is constructed by the version of libtool installed at '[R_HOME](#)/bin'.

R CMD LINK --help gives usage information.

Note

Some binary distributions of R have LINK in a separate bundle, e.g. an R-devel RPM.

This is not available on Windows.

See Also

[COMPILE](#).

Examples

```
## Not run: ## examples of front-ends linked against R.
## First a C program
CC=`R CMD config CC`
R CMD LINK $CC -o foo foo.o `R CMD config --ldflags`

## if Fortran code has been compiled into ForFoo.o
FLIBS=`R CMD config FLIBS`
R CMD LINK $CC -o foo foo.o ForFoo.o `R CMD config --ldflags` $FLIBS

## And for a C++ front-end
CXX=`R CMD config CXX`
```

```
R CMD COMPILE foo.cc
R CMD LINK $CXX -o foo foo.o `R CMD config --ldflags`

## End(Not run)
```

localeToCharset*Select a Suitable Encoding Name from a Locale Name*

Description

This functions aims to find a suitable coding for the locale named, by default the current locale, and if it is a UTF-8 locale a suitable single-byte encoding.

Usage

```
localeToCharset(locale = Sys.getlocale("LC_CTYPE"))
```

Arguments

locale character string naming a locale.

Details

The operation differs by OS.

On Windows, a locale is specified like "English_United Kingdom.1252". The final component gives the codepage, and this defines the encoding.

On Unix-alikes: Locale names are normally like es_MX.iso88591. If final component indicates an encoding and it is not utf8 we just need to look up the equivalent encoding name. Otherwise, the language (here es) is used to choose a primary or fallback encoding.

In the C locale the answer will be "ASCII".

Value

A character vector naming an encoding and possibly a fallback single-encoding, NA if unknown.

Note

The encoding names are those used by libiconv, and ought also to work with glibc but maybe not with commercial Unixen.

See Also

[Sys.getlocale](#), [iconv](#).

Examples

```
localeToCharset()
```

ls.str

*List Objects and their Structure***Description**

ls.str and lsf.str are variations of [ls](#) applying [str\(\)](#) to each matched name: see section [Value](#).

Usage

```
ls.str(pos = -1, name, envir, all.names = FALSE,
       pattern, mode = "any")

lsf.str(pos = -1, envir, ...)

## S3 method for class 'ls_str'
print(x, max.level = 1, give.attr = FALSE, ...,
      digits = max(1, getOption("str")$digits.d))
```

Arguments

| | |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pos | integer indicating search path position, or -1 for the current environment. |
| name | optional name indicating search path position, see ls . |
| envir | environment to use, see ls . |
| all.names | logical indicating if names which begin with a . are omitted; see ls . |
| pattern | a regular expression passed to ls . Only names matching pattern are considered. |
| max.level | maximal level of nesting which is applied for displaying nested structures, e.g., a list containing sub lists. Default 1: Display only the first nested level. |
| give.attr | logical; if TRUE (default), show attributes as sub structures. |
| mode | character specifying the mode of objects to consider. Passed to exists and get . |
| x | an object of class "ls_str". |
| ... | further arguments to pass. lsf.str passes them to ls.str which passes them on to ls . The (non-exported) print method print.ls_str passes them to str . |
| digits | the number of significant digits to use for printing. |

Value

ls.str and lsf.str return an object of class "ls_str", basically the character vector of matching names (functions only for lsf.str), similarly to [ls](#), with a print() method that calls [str\(\)](#) on each object.

Author(s)

Martin Maechler

See Also

[str](#), [summary](#), [args](#).

Examples

```
require(stats)

lsf.str() #- how do the functions look like which I am using?
ls.str(mode = "list")  #- what are the structured objects I have defined?

## create a few objects
example(glm, echo = FALSE)
ll <- as.list(LETTERS)
print(ls.str(), max.level = 0)# don't show details

## which base functions have "file" in their name ?
lsf.str(pos = length(search()), pattern = "file")

## demonstrating that ls.str() works inside functions
## ["browser/debug mode"]:
tt <- function(x, y = 1) { aa <- 7; r <- x + y; ls.str() }
(nms <- sapply(strsplit(capture.output(tt(2))," *:"), `[, 1)`)
stopifnot(nms == c("aa", "r", "x", "y"))
```

`maintainer`

Show Package Maintainer

Description

Show the name and email address of the maintainer of an installed package.

Usage

```
maintainer(pkg)
```

Arguments

`pkg` a character string, the name of an installed package.

Details

Accesses the [package description](#) to return the name and email address of the maintainer.

Questions about contributed packages should often be addressed to the package maintainer; questions about base packages should usually be addressed to the R-help or R-devel mailing lists. Bug reports should be submitted using the [bug.report](#) function.

Value

A character string giving the name and email address of the maintainer of the package, or NA_character_ if no such package is installed.

Author(s)

David Scott <d.scott@auckland.ac.nz> from code on R-help originally due to Charlie Sharpsteen <source@sharpsteen.net>; multiple corrections by R-core.

[packageDescription](#), [bug.report](#)

Examples

```
maintainer("MASS")
```

| | |
|--------------------|---------------------------------|
| make.packages.html | <i>Update HTML Package List</i> |
|--------------------|---------------------------------|

Description

Re-create the HTML list of packages.

Usage

```
make.packages.html(lib.loc = .libPaths(), temp = FALSE,  
                   verbose = TRUE, docdir = R.home("doc"))
```

Arguments

| | |
|---------|----------------------------------------------------------------------------------------------------------|
| lib.loc | character vector. List of libraries to be included. |
| temp | logical: should the package indices be created in a temporary location for use by the HTTP server? |
| verbose | logical. If true, print out a message. |
| docdir | If temp is false, directory in whose 'html' directory the 'packages.html' file is to be created/updated. |

Details

This creates the ‘packages.html’ file, either a temporary copy for use by [help.start](#), or the copy in ‘R.home("doc")/html’ (for which you will need write permission).

It can be very slow, as all the package ‘DESCRIPTION’ files in all the library trees are read.

For temp = TRUE there is some caching of information, so the file will only be re-created if lib.loc or any of the directories it lists have been changed.

Value

Invisible logical, with FALSE indicating a failure to create the file, probably due to lack of suitable permissions.

See Also

[help.start](#)

Examples

```
## Not run:
make.packages.html()
# this can be slow for large numbers of installed packages.

## End(Not run)
```

make.socket

Create a Socket Connection

Description

With server = FALSE attempts to open a client socket to the specified port and host. With server = TRUE the R process listens on the specified port for a connection and then returns a server socket. It is a good idea to use [on.exit](#) to ensure that a socket is closed, as you only get 64 of them.

Usage

```
make.socket(host = "localhost", port, fail = TRUE, server = FALSE)
```

Arguments

| | |
|--------|---------------------------------|
| host | name of remote host |
| port | port to connect to/listen on |
| fail | failure to connect is an error? |
| server | a server socket? |

Value

An object of class "socket", a list with components:

| | |
|--------|-----------------------------------------------------------------------------------|
| socket | socket number. This is for internal use. On a Unix-alike it is a file descriptor. |
| port | port number of the connection. |
| host | name of remote computer. |

Warning

I don't know if the connecting host name returned when `server = TRUE` can be trusted. I suspect not.

Author(s)

Thomas Lumley

References

Adapted from Luke Tierney's code for XLISP-Stat, in turn based on code from Robbins and Robbins "Practical UNIX Programming".

See Also

[close.socket](#), [read.socket](#).

Compiling in support for sockets was optional prior to R 3.3.0: see [capabilities\("sockets"\)](#) to see if it is available.

Examples

```
daytime <- function(host = "localhost"){
  a <- make.socket(host, 13)
  on.exit(close.socket(a))
  read.socket(a)
}
## Official time (UTC) from US Naval Observatory
## Not run: daytime("tick.usno.navy.mil")
```

menu

Menu Interaction Function

Description

menu presents the user with a menu of choices labelled from 1 to the number of choices. To exit without choosing an item one can select '0'.

Usage

```
menu(choices, graphics = FALSE, title = NULL)
```

Arguments

| | |
|-----------------------|--------------------------------------------------------------------------------|
| <code>choices</code> | a character vector of choices |
| <code>graphics</code> | a logical indicating whether a graphics menu should be used if available. |
| <code>title</code> | a character string to be used as the title of the menu. NULL is also accepted. |

Details

If `graphics = TRUE` and a windowing system is available (Windows, macOS or X11 *via* Tcl/Tk) a listbox widget is used, otherwise a text menu. It is an error to use `menu` in a non-interactive session.

Ten or fewer items will be displayed in a single column, more in multiple columns if possible within the current display width.

No title is displayed if `title` is NULL or `""`.

Value

The number corresponding to the selected item, or 0 if no choice was made.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

[select.list](#), which is used to implement the graphical menu, and allows multiple selections.

Examples

```
## Not run:
switch(menu(c("List letters", "List LETTERS")) + 1,
        cat("Nothing done\n"), letters, LETTERS)

## End(Not run)
```

methods

List Methods for S3 Generic Functions or Classes

Description

List all available methods for a S3 and S4 generic function, or all methods for an S3 or S4 class.

Usage

```

methods(generic.function, class, all.names = FALSE, dropPath = FALSE)
.S3methods(generic.function, class, envir = parent.frame(),
            all.names = FALSE, dropPath = FALSE)

## S3 method for class 'MethodsFunction'
format(x, byclass = attr(x, "byclass"), ...)
## S3 method for class 'MethodsFunction'
print(x, byclass = attr(x, "byclass"), ...)

```

Arguments

| | |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>generic.function</code> | a generic function, or a character string naming a generic function. |
| <code>class</code> | a symbol or character string naming a class: only used if <code>generic.function</code> is not supplied. |
| <code>envir</code> | the environment in which to look for the definition of the generic function, when the generic function is passed as a character string. |
| <code>all.names</code> | a logical indicating if all object names are returned. When FALSE as by default, names beginning with a <code>'.'</code> are omitted. |
| <code>dropPath</code> | a logical indicating if the search() path, apart from .GlobalEnv and <code>package:base</code> (i.e., baseenv()), should be skipped when searching for method definitions. The default FALSE is back compatible and typically desired for <code>print()</code> ing, with or without asterisk; <code>dropPath=TRUE</code> has been hard coded in R 4.3.0 and is faster for non-small search() paths. |
| <code>x</code> | typically the result of <code>methods(..)</code> , an R object of S3 class "MethodsFunction", see 'Value' below. |
| <code>byclass</code> | an optional logical allowing to override the "byclass" attribute determining how the result is printed, see 'Details'. |
| <code>...</code> | potentially further arguments passed to and from methods; unused currently. |

Details

`methods()` finds S3 and S4 methods associated with either the `generic.function` or `class` argument. Methods found are those provided by all loaded namespaces via registration, see [UseMethod](#); normally, this includes all packages on the current `search()` path. `.S3methods()` finds only S3 methods, `.S4methods()` finds only S4 methods.

When invoked with the `generic.function` argument, the "byclass" attribute (see Details) is FALSE, and the `print` method by default displays the signatures (full names) of S3 and S4 methods. S3 methods are printed by pasting the generic function and class together, separated by a `'.'`, as `generic.class`. The S3 method name is followed by an asterisk `*` if the method definition is not exported from the package namespace in which the method is defined. S4 method signatures are printed as `generic,class-method`; S4 allows for multiple dispatch, so there may be several classes in the signature `generic,A,B-method`.

When invoked with the `class` argument, "byclass" is TRUE, and the `print` method by default displays the names of the generic functions associated with the class, `generic`.

The source code for all functions is available. For S3 functions exported from the namespace, enter the method at the command line as `generic.class`. For S3 functions not exported from the namespace, see `getAnywhere` or `getS3method`. For S4 methods, see `getMethod`.

Help is available for each method, in addition to each generic. For interactive help, use the documentation shortcut `?<name>` with the name of the generic and tab completion, `?<generic><tab>` to select the method for which help is desired.

The S3 functions listed are those which *are named like methods* and may not actually be methods (known exceptions are discarded in the code).

Value

An object of class "MethodsFunction", a character vector of method names with "byclass" and "info" attributes. The "byclass" attribute is a [logical](#) indicating if the results were obtained with argument `class` defined. The "info" attribute is a data frame with columns:

generic [character](#) vector of the names of the generic.

visible `logical()`, is the method "visible" to the user? When true, it typically is exported from the namespace of the package in which it is defined, and the package is [attach\(\)](#)ed to the [search\(\)](#) path.

isS4 `logical()`, true when the method is an S4 method.

from a [factor](#), the location or package name where the method was found.

Note

The original methods function was written by Martin Maechler.

}

```

mirrorAdmin

Managing Repository Mirrors

Description

Functions helping to maintain CRAN, some of them may also be useful for administrators of other repository networks.

Usage

```

mirror2html(mirrors = NULL, file = "mirrors.html",
  head = "mirrors-head.html", foot = "mirrors-foot.html")
checkCRAN(method)

```

Arguments

| | |
|---------|------------------------------------------------------------|
| mirrors | A data frame, by default the CRAN list of mirrors is used. |
| file | A connection or a character string. |
| head | Name of optional header file. |
| foot | Name of optional footer file. |
| method | Download method, see <code>download.file</code> . |

Details

`mirror2html` creates the HTML file for the CRAN list of mirrors and invisibly returns the HTML text.

`checkCRAN` performs a sanity checks on all CRAN mirrors.

modifyList*Recursively Modify Elements of a List*

Description

Modifies a possibly nested list recursively by changing a subset of elements at each level to match a second list.

Usage

```
modifyList(x, val, keep.null = FALSE)
```

Arguments

| | |
|-----------|-------------------------------------------------------------------------------------------------------------------------------|
| x | A named list , possibly empty. |
| val | A named list with components to replace corresponding components in x or add new components. |
| keep.null | If TRUE, NULL elements in val become NULL elements in x. Otherwise, the corresponding element, if present, is deleted from x. |

Value

A modified version of x, with the modifications determined as follows (here, list elements are identified by their names). Elements in val which are missing from x are added to x. For elements that are common to both but are not both lists themselves, the component in x is replaced (or possibly deleted, depending on the value of keep.null) by the one in val. For common elements that are in both lists, x[[name]] is replaced by modifyList(x[[name]], val[[name]]).

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

Examples

```
foo <- list(a = 1, b = list(c = "a", d = FALSE))
bar <- modifyList(foo, list(e = 2, b = list(d = TRUE)))
str(foo)
str(bar)
```

news

*Build and Query R or Package News Information***Description**

Build and query the news data base for R or add-on packages.

Usage

```
news(query, package = "R", lib.loc = NULL, format = NULL,
      reader = NULL, db = NULL)

## S3 method for class 'news_db'
print(x, doBrowse = interactive(),
      browser = getOption("browser"), ...)
```

Arguments

| | |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| query | an optional expression for selecting news entries. |
| package | a character string giving the name of an installed add-on package, or "R" or "R-3" or "R-2". |
| lib.loc | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. |
| format | Not yet used. |
| reader | Not yet used. |
| db, x | a news db obtained from news(). |
| doBrowse | logical specifying that the news should be opened in the browser (by browseURL , accessible as via help.start) instead of printed to the console. |
| browser | the browser to be used, see browseURL . |
| ... | potentially further arguments passed to print(). |

Details

If package is "R" (default), a news db is built with the news since the 4.0.0 release of R, corresponding to the 'NEWS' file in the R.home("doc") directory. "R-3" or "R-2" give the news for R 3.x.y or R 2.x.y respectively. Otherwise, if the given add-on package can be found in the given libraries, it is attempted to read its news in structured form from files 'inst/NEWS.Rd', 'NEWS.md' (since R version 3.6.0, needs packages **commonmark** and **xml2** to be available), 'NEWS' or 'inst/NEWS' (in that order). See section 'NEWS Formats' for the file specifications.

Using query, one can select news entries from the db. If missing or NULL, the complete db is returned. Otherwise, query should be an expression involving (a subset of) the variables Version, Category, Date and Text, and when evaluated within the db returning a logical vector with length the number of entries in the db. The entries for which evaluation gave TRUE are selected. When evaluating, Version and Date are coerced to [numeric_version](#) and [Date](#) objects, respectively, so that the comparison operators for these classes can be employed.

Value

A data frame inheriting from class "news_db", with character variables Version, Category, Date, Text and HTML, where the last two each contain the entry texts read (in plain-text and HTML format, respectively), and the other variables may be NA if they were missing or could not be determined. The data frame has `attributes` "package" (and "subset" if the query lead to proper subsetting).

NEWS Formats

‘inst/NEWS.Rd’: File ‘inst/NEWS.Rd’ should be an Rd file given the entries as Rd `\itemize` lists, grouped according to version using `\section` elements. Section titles start with a suitable prefix followed by a space and the version number, and optionally end with a (parenthesized) ISO 8601 (%Y-%m-%d, see `strptime`) format date (optionally including a note), for example:

```
\section{Changes in version 2.0 (2020-02-02, <note>)}{
  \itemize{
    \item ...
  }
}
```

The entries can be further grouped according to categories using `\subsection` elements named as the categories. The ‘NEWS.Rd’ file is assumed to be UTF-8-encoded (but an included `\encoding` specification takes precedence).

‘NEWS.md’: File ‘NEWS.md’ should contain the news in Markdown (following the CommonMark (<https://commonmark.org/>) specification), with the primary heading level giving the version number after a prefix followed by a space, and optionally followed by a space and a parenthesized ISO 8601 format date. Where available, secondary headings are taken to indicate categories. To accommodate for common practice, news entries are only split down to the category level.

‘NEWS’: The plain text ‘NEWS’ files in add-on packages use a variety of different formats; the default news reader should be capable to extract individual news entries from a majority of packages from the standard repositories, which use (slight variations of) the following format:

- Entries are grouped according to version, with version header “Changes in version” at the beginning of a line, followed by a version number, optionally followed by an ISO 8601 format date, possibly parenthesized.
- Entries may be grouped according to category, with a category header (different from a version header) starting at the beginning of a line.
- Entries are written as itemize-type lists, using one of ‘o’, ‘*’, ‘-’ or ‘+’ as item tag. Entries must be indented, and ideally use a common indentation for the item texts.

Package **tools** provides an (internal) utility function `news2Rd` to convert plain text ‘NEWS’ files to Rd. For ‘NEWS’ files in a format which can successfully be handled by the default reader, package maintainers can use `tools::news2Rd(dir, "NEWS.Rd")`, possibly with additional argument `codify = TRUE`, with `dir` a character string specifying the path to a package’s root directory. Upon success, the ‘NEWS.Rd’ file can further be improved and then be moved to the ‘inst’ subdirectory of the package source directory.

Additional formats and readers may be supported in the future.

Examples

```
## Build a db of all R news entries.
db <- news()

## Bug fixes with PR number in 4.0.0.
db4 <- news(Version == "4.0.0" & grepl("^BUG", Category) & grepl("PR#", Text),
           db = db)
nrow(db4)

## print db4 to show in an HTML browser.

## News from a date range ('Matrix' is there in a regular R installation):
if(length(iM <- find.package("Matrix", quiet = TRUE)) && nzchar(iM)) {
  dM <- news(package="Matrix")
  stopifnot(identical(dM, news(db=dM)))
  dM2014 <- news("2014-01-01" <= Date & Date <= "2014-12-31", db = dM)
  stopifnot(paste0("1.1-", 2:4) %in% dM2014[, "Version"])
}

## Which categories have been in use? % R-core maybe should standardize a bit more
sort(table(db[, "Category"]), decreasing = TRUE)
## Entries with version >= 4.0.0
table(news(Version >= "4.0.0", db = db)$Version)

## do the same for R 3.x.y, more slowly
db3 <- news(package = "R-3")
sort(table(db3[, "Category"]), decreasing = TRUE)
## Entries with version >= 3.6.0
table(news(Version >= "3.6.0", db = db3)$Version)
```

nsl

Look up the IP Address by Hostname (on Unix-alikes)

Description

Interface to the system `gethostbyname`, currently available only on unix-alikes, i.e., not on Windows.

Usage

```
nsl(hostname)
```

Arguments

`hostname` the name of the host.

Details

This was included as a test of internet connectivity, to fail if the node running R is not connected. It will also return NULL if BSD networking is not supported, including the header file ‘arpa/inet.h’.

This function is not available on Windows.

Value

The IP address, as a character string, or NULL if the call fails.

Examples

```
if(.Platform$OS.type == "unix") # includes Mac
  print( nsl("www.r-project.org") )
```

| | |
|--------------------------|-------------------------------------------------|
| <code>object.size</code> | <i>Report the Space Allocated for an Object</i> |
|--------------------------|-------------------------------------------------|

Description

Provides an estimate of the memory that is being used to store an R object.

Usage

```
object.size(x)

## S3 method for class 'object_size'
format(x, units = "b", standard = "auto", digits = 1L, ...)
## S3 method for class 'object_size'
print(x, quote = FALSE, units = "b", standard = "auto",
      digits = 1L, ...)
```

Arguments

| | |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code> | an R object. |
| <code>quote</code> | logical, indicating whether or not the result should be printed with surrounding quotes. |
| <code>units</code> | the units to be used in formatting and printing the size. Allowed values for the different standards are standard = "legacy": "b", "Kb", "Mb", "Gb", "Tb", "Pb", "B", "KB", "MB", "GB", "TB" and "PB". standard = "IEC": "B", "KiB", "MiB", "GiB", "TiB", "PiB", "EiB", "ZiB" and "YiB". standard = "SI": "B", "kB", "MB", "GB", "TB", "PB", "EB", "ZB", "YB", "RB", and "QB". |

| | |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| | For all standards, <code>units = "auto"</code> is also allowed. If <code>standard = "auto"</code> , any of the "legacy" and IEC units are allowed. See 'Formatting and printing object sizes' for details. |
| <code>standard</code> | the byte-size unit standard to be used. A character string, possibly abbreviated from "legacy", "IEC", "SI" and "auto". See 'Formatting and printing object sizes' for details. |
| <code>digits</code> | the number of digits after the decimal point, passed to round . |
| <code>...</code> | arguments to be passed to or from other methods. |

Details

Exactly which parts of the memory allocation should be attributed to which object is not clear-cut. This function merely provides a rough indication: it should be reasonably accurate for atomic vectors, but does not detect if elements of a list are shared, for example. (Sharing amongst elements of a character vector is taken into account, but not that between character vectors in a single object.)

The calculation is of the size of the object, and excludes the space needed to store its name in the symbol table.

Associated space (e.g., the environment of a function and what the pointer in a `EXTPTRSXP` points to) is not included in the calculation.

Object sizes are larger on 64-bit builds than 32-bit ones, but will very likely be the same on different platforms with the same word length and pointer size.

Sizes of objects using a compact internal representation may be over-estimated.

Value

An object of class "object_size" with a length-one double value, an estimate of the memory allocation attributable to the object in bytes.

Formatting and printing object sizes

Object sizes can be formatted using byte-size units from R's legacy standard, the IEC standard, or the SI standard. As illustrated by below tables, the legacy and IEC standards use *binary* units (multiples of 1024), whereas the SI standard uses *decimal* units (multiples of 1000).

For methods `format` and `print`, argument `standard` specifies which standard to use and argument `units` specifies which byte-size unit to use. `units = "auto"` chooses the largest units in which the result is one or more (before rounding). Byte sizes are rounded to `digits` decimal places. `standard = "auto"` chooses the standard based on `units`, if possible, otherwise, the legacy standard is used.

Summary of R's legacy and IEC units:

| object size | legacy | IEC |
|-------------|---------|-------|
| 1 | 1 bytes | 1 B |
| 1024 | 1 Kb | 1 KiB |
| 1024^2 | 1 Mb | 1 MiB |
| 1024^3 | 1 Gb | 1 GiB |
| 1024^4 | 1 Tb | 1 TiB |
| 1024^5 | 1 Pb | 1 PiB |

| | |
|-------------------|-------|
| 1024 ⁶ | 1 EiB |
| 1024 ⁷ | 1 ZiB |
| 1024 ⁸ | 1 YiB |

Summary of SI units:

| object size | SI |
|--------------------|------|
| 1 | 1 B |
| 1000 | 1 kB |
| 1000 ² | 1 MB |
| 1000 ³ | 1 GB |
| 1000 ⁴ | 1 TB |
| 1000 ⁵ | 1 PB |
| 1000 ⁶ | 1 EB |

Examples

```
object.size(letters)
object.size(ls)
format(object.size(library), units = "auto")

sl <- object.size(rep(letters, 1000))

print(sl)                                ## 209288 bytes
print(sl, units = "auto")                 ## 204.4 Kb
print(sl, units = "auto", standard = "IEC") ## 204.4 KiB
print(sl, units = "auto", standard = "SI")  ## 209.3 kB

(fsl <- sapply(c("Kb", "KB", "KiB"),
  function(u) format(sl, units = u)))
stopifnot(identical( ## assert that all three are the same :
```

```

unique(substr(as.vector(fsl), 1,5)),
format(round(as.vector(sl)/1024, 1))))

## find the 10 largest objects in the base package
z <- sapply(ls("package:base"), function(x)
  object.size(get(x, envir = baseenv()))))
if(interactive()) {
  as.matrix(rev(sort(z))[1:10])
} else # (more constant over time):
  names(rev(sort(z))[1:10])

```

package.skeleton

Create a Skeleton for a New Source Package

Description

package.skeleton automates some of the setup for a new source package. It creates directories, saves functions, data, and R code files to appropriate places, and creates skeleton help files and a ‘Read-and-delete-me’ file describing further steps in packaging.

Usage

```

package.skeleton(name = "anRpackage", list,
  environment = .GlobalEnv,
  path = ".", force = FALSE,
  code_files = character(), encoding = "unknown")

```

Arguments

| | |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| name | character string: the package name and directory name for your package. Must be a valid package name. |
| list | character vector naming the R objects to put in the package. Usually, at most one of list, environment, or code_files will be supplied. See ‘Details’. |
| environment | an environment where objects are looked for. See ‘Details’. |
| path | path to put the package directory in. |
| force | If FALSE will not overwrite an existing directory. |
| code_files | a character vector with the paths to R code files to build the package around. See ‘Details’. |
| encoding | optionally a character string with an encoding for an optional ‘Encoding:’ line in ‘DESCRIPTION’ when non-ASCII characters will be used; typically one of "latin1", "latin2", or "UTF-8"; see the WRE manual. |

Details

The arguments `list`, `environment`, and `code_files` provide alternative ways to initialize the package. If `code_files` is supplied, the files so named will be sourced to form the environment, then used to generate the package skeleton. Otherwise `list` defaults to the objects in `environment` (including those whose names start with `.`), but can be supplied to select a subset of the objects in that environment.

Stubs of help files are generated for functions, data objects, and S4 classes and methods, using the `prompt`, `promptClass`, and `promptMethods` functions. If an object from another package is intended to be imported and re-exported without changes, the `promptImport` function should be used after `package.skeleton` to generate a simple help file linking to the original one.

The package sources are placed in subdirectory `name` of `path`. If `code_files` is supplied, these files are copied; otherwise, objects will be dumped into individual source files. The file names in `code_files` should have suffix `".R"` and be in the current working directory.

The filenames created for source and documentation try to be valid for all OSes known to run R. Invalid characters are replaced by `'_'`, invalid names are preceded by `'zz'`, names are converted to lower case (to avoid case collisions on case-insensitive file systems) and finally the converted names are made unique by `make.unique(sep = "_")`. This can be done for code and help files but not data files (which are looked for by name). Also, the code and help files should have names starting with an ASCII letter or digit, and this is checked and if necessary `z` prepended.

Functions with names starting with a dot are placed in file `'R/name-internal.R'`.

When you are done, delete the `'Read-and-delete-me'` file, as it should not be distributed.

Value

Used for its side-effects.

References

Read the `'Writing R Extensions'` manual for more details.

Once you have created a *source* package you need to install it: see the `'R Installation and Administration'` manual, `INSTALL` and `install.packages`.

See Also

`prompt`, `promptClass`, and `promptMethods`.

`package_native_routine_registration_skeleton` for helping in preparing packages with compiled code.

Examples

```
require(stats)
## two functions and two "data sets" :
f <- function(x, y) x+y
g <- function(x, y) x-y
d <- data.frame(a = 1, b = 2)
e <- rnorm(1000)
```

```
package.skeleton(list = c("f","g","d","e"), name = "mypkg")
```

| | |
|--------------------|----------------------------|
| packageDescription | <i>Package Description</i> |
|--------------------|----------------------------|

Description

Parses and returns the ‘DESCRIPTION’ file of a package as a "packageDescription".

Utility functions return (transformed) parts of that.

Usage

```
packageDescription(pkg, lib.loc = NULL, fields = NULL,
                  drop = TRUE, encoding = "")
packageVersion(pkg, lib.loc = NULL)
packageDate(pkg, lib.loc = NULL,
            date.fields = c("Date", "Packaged", "Date/Publication", "Built"),
            tryFormats = c("%Y-%m-%d", "%Y/%m/%d", "%D", "%m/%d/%y"),
            desc = packageDescription(pkg, lib.loc=lib.loc, fields=date.fields))
asDateBuilt(built)
```

Arguments

| | |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pkg | a character string with the package name. |
| lib.loc | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. If the default is used, the loaded packages and namespaces are searched before the libraries. |
| fields | a character vector giving the tags of fields to return (if other fields occur in the file they are ignored). |
| drop | If <code>TRUE</code> and the length of <code>fields</code> is 1, then a single character string with the value of the respective field is returned instead of an object of class "packageDescription". |
| encoding | If there is an <code>Encoding</code> field, to what encoding should re-encoding be attempted? If <code>NA</code> , no re-encoding. The other values are as used by iconv , so the default "" indicates the encoding of the current locale. |
| date.fields | character vector of field tags to be tried. The first for which <code>as.Date(.)</code> is not <code>NA</code> will be returned. (Partly experimental, see <i>Note</i> .) |
| tryFormats | date formats to try, see <code>as.Date.character()</code> . |
| desc | optionally, a named list with components named from <code>date.fields</code> ; where the default is fine, a complete <code>packageDescription()</code> maybe specified as well. |
| built | for <code>asDateBuilt()</code> , a character string as from <code>packageDescription(*, fields="Built")</code> . |

Details

A package will not be ‘found’ unless it has a ‘DESCRIPTION’ file which contains a valid Version field. Different warnings are given when no package directory is found and when there is a suitable directory but no valid ‘DESCRIPTION’ file.

An [attached](#) environment named to look like a package (e.g., `package:utils2`) will be ignored.

`packageVersion()` is a convenience shortcut, allowing things like `if (packageVersion("MASS") < "7.3") { do.things }`.

For `packageDate()`, if desc is valid, both `pkg` and `lib.loc` are not made use of.

Value

If a ‘DESCRIPTION’ file for the given package is found and can successfully be read, `packageDescription` returns an object of class `"packageDescription"`, which is a named list with the values of the (given) fields as elements and the tags as names, unless `drop = TRUE`.

If parsing the ‘DESCRIPTION’ file was not successful, it returns a named list of NAs with the field tags as names if `fields` is not null, and NA otherwise.

`packageVersion()` returns a (length-one) object of class `"package_version"`.

`packageDate()` will return a `"Date"` object from `as.Date()` or NA.

`asDateBuilt(built)` returns a `"Date"` object or signals an error if `built` is invalid.

Note

The default behavior of `packageDate()`, notably for `date.fields`, is somewhat experimental and may change.

Examples

```
packageDescription("stats")
packageDescription("stats", fields = c("Package", "Version"))

packageDescription("stats", fields = "Version")
packageDescription("stats", fields = "Version", drop = FALSE)

if(requireNamespace("MASS") && packageVersion("MASS") < "7.3.29")
  message("you need to update 'MASS'")

pu <- packageDate("utils")
str(pu)
stopifnot(identical(pu, packageDate(desc = packageDescription("utils"))),
  identical(pu, packageDate("stats"))) # as "utils" and "stats" are
# both 'base R' and "Built" at same time
```

| | |
|-------------|----------------------------------------------------|
| packageName | <i>Find Package Associated with an Environment</i> |
|-------------|----------------------------------------------------|

Description

Many environments are associated with a package; this function attempts to determine that package.

Usage

```
packageName(env = parent.frame())
```

Arguments

| | |
|-----|-------------------------------------|
| env | The environment whose name we seek. |
|-----|-------------------------------------|

Details

Environment `env` would be associated with a package if `topenv(env)` is the namespace environment for that package. Thus when `env` is the environment associated with functions inside a package, or local functions defined within them, `packageName` will normally return the package name.

Not all environments are associated with a package: for example, the global environment, or the evaluation frames of functions defined there. `packageName` will return `NULL` in these cases.

Value

A length one character vector containing the name of the package, or `NULL` if there is no name.

See Also

[getPackageName](#) is a more elaborate function that can construct a name if none is found.

Examples

```
packageName()  
packageName(environment(mean))
```

| | |
|---------------|---------------------------------|
| packageStatus | <i>Package Management Tools</i> |
|---------------|---------------------------------|

Description

Summarize information about installed packages and packages available at various repositories, and automatically upgrade outdated packages.

Usage

```
packageStatus(lib.loc = NULL, repositories = NULL, method,
              type = getOption("pkgType"), ...)

## S3 method for class 'packageStatus'
summary(object, ...)

## S3 method for class 'packageStatus'
update(object, lib.loc = levels(object$inst$LibPath),
        repositories = levels(object$avail$Repository), ...)

## S3 method for class 'packageStatus'
upgrade(object, ask = TRUE, ...)
```

Arguments

| | |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| lib.loc | a character vector describing the location of R library trees to search through, or NULL. The default value of NULL corresponds to all libraries currently known. |
| repositories | a character vector of URLs describing the location of R package repositories on the Internet or on the local machine. These should be full paths to the appropriate ‘contrib’ sections of the repositories. The default (NULL) derives URLs from option "repos" and type. |
| method | download method, see download.file . |
| type | type of package distribution: see install.packages . |
| object | an object of class "packageStatus" as returned by packageStatus. |
| ask | if TRUE, the user is prompted which packages should be upgraded and which not. |
| ... | for packageStatus: arguments to be passed to available.packages and installed.packages . for the upgrade method, arguments to be passed to install.packages for other methods: currently not used. |

Details

There are print and summary methods for the "packageStatus" objects: the print method gives a brief tabular summary and the summary method prints the results.

The `update` method updates the "packageStatus" object. The `upgrade` method is similar to [update.packages](#): it offers to install the current versions of those packages which are not currently up-to-date.

Value

An object of class "packageStatus". This is a list with two components

| | |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>inst</code> | a data frame with columns as the <i>matrix</i> returned by installed.packages plus "Status", a factor with levels <code>c("ok", "upgrade", "unavailable")</code> . Only the newest version of each package is reported, in the first repository in which it appears. |
| <code>avail</code> | a data frame with columns as the <i>matrix</i> returned by available.packages plus "Status", a factor with levels <code>c("installed", "not installed")</code> . |

For the `summary` method the result is also of class "summary.packageStatus" with additional components

| | |
|--------------------|---------------------------------------------|
| <code>Libs</code> | a list with one element for each library |
| <code>Repos</code> | a list with one element for each repository |

with the elements being lists of character vectors of package name for each status.

See Also

[installed.packages](#), [available.packages](#)

Examples

```
x <- packageStatus(repositories = contrib.url(findCRANmirror("web")))
print(x)
summary(x)

## Not run:
upgrade(x)
x <- update(x)
print(x)

## End(Not run)
```

Description

Displays a representation of the object named by `x` in a pager via [file.show](#).

Usage

```
page(x, method = c("dput", "print"), ...)
```

Arguments

- x An R object, or a character string naming an object.
- method The default method is to dump the object *via* [dput](#). An alternative is to use `print` and capture the output to be shown in the pager. Can be abbreviated.
- ... additional arguments for [dput](#), [print](#) or [file.show](#) (such as title).

Details

If `x` is a length-one character vector, it is used as the name of an object to look up in the environment from which `page` is called. All other objects are displayed directly.

A default value of `title` is passed to `file.show` if one is not supplied in ...

See Also

[file.show](#), [edit](#), [fix](#).

To go to a new page when graphing, see [frame](#).

Examples

```
## Not run: ## four ways to look at the code of 'page'
page(page)           # as an object
page("page")        # a character string
v <- "page"; page(v)  # a length-one character vector
page(utils::page)     # a call

## End(Not run)
```

| | |
|--------|----------------|
| person | <i>Persons</i> |
|--------|----------------|

Description

A class and utility methods for holding information about persons like name and email address.

Usage

```
person(given = NULL, family = NULL, middle = NULL,
       email = NULL, role = NULL, comment = NULL,
       first = NULL, last = NULL)

as.person(x)
## Default S3 method:
as.person(x)
```

```
## S3 method for class 'person'
format(x,
      include = c("given", "family", "email", "role", "comment"),
      braces = list(given = "", family = "", email = c("<", ">"),
                    role = c("[", "]"), comment = c("(", ")")),
      collapse = list(given = " ", family = " ", email = ", ",
                      role = ", ", comment = ", "),
      ...,
      style = c("text", "R"))

## S3 method for class 'person'
toBibtex(object, escape = FALSE, ...)
```

Arguments

| | |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>given</code> | a character vector with the <i>given</i> names, or a list thereof. |
| <code>family</code> | a character string with the <i>family</i> name, or a list thereof. |
| <code>middle</code> | a character string with the collapsed middle name(s). Deprecated, see Details . |
| <code>email</code> | a character string (or vector) giving an e-mail address (each), or a list thereof. |
| <code>role</code> | a character vector specifying the role(s) of the person (see Details), or a list thereof. |
| <code>comment</code> | a character string (or vector) providing comments, or a list thereof. |
| <code>first</code> | a character string giving the first name. Deprecated, see Details . |
| <code>last</code> | a character string giving the last name. Deprecated, see Details . |
| <code>x</code> | an object for the <code>as.person</code> generic; a character string for the <code>as.person</code> default method; an object of class "person" otherwise. |
| <code>include</code> | a character vector giving the fields to be included when formatting. |
| <code>braces</code> | a list of characters (see Details). |
| <code>collapse</code> | a list of characters (see Details). |
| <code>...</code> | currently not used. |
| <code>style</code> | a character string specifying the print style, with "R" yielding formatting as R code. |
| <code>object</code> | an R object inhering from class "person". |
| <code>escape</code> | a logical indicating whether non-ASCII characters should be translated to LaTeX escape sequences. |

Details

Objects of class "person" can hold information about an arbitrary positive number of persons. These can be obtained by one call to `person()` with list arguments, or by first creating objects representing single persons and combining these via `c()`.

The `format()` method collapses information about persons into character vectors (one string for each person): the fields in `include` are selected, each collapsed to a string using the respective element of `collapse` and subsequently “embraced” using the respective element of `braces`, and finally collapsed into one string separated by white space. If `braces` and/or `collapse` do not specify characters for all fields, the defaults shown in the usage are imputed. If `collapse` is `FALSE` or `NA` the corresponding field is not collapsed but only the first element is used. The `print()` method calls the `format()` method and prints the result, the `toBibtex()` method creates a suitable BibTeX representation.

Person objects can be subscripted by fields (using `$`) or by position (using `[]`).

`as.person()` is a generic function. Its default method tries to reverse the default person formatting, and can also handle formatted person entries collapsed by comma or “and” (with appropriate white space).

Personal names are rather tricky, e.g., https://en.wikipedia.org/wiki/Personal_name.

The current implementation (starting from R 2.12.0) of the “person” class uses the notions of *given* (including middle names) and *family* names, as specified by `given` and `family` respectively. Earlier versions used a scheme based on first, middle and last names, as appropriate for most of Western culture where the given name precedes the family name, but not universal, as some other cultures place it after the family name, or use no family name. To smooth the transition to the new scheme, arguments `first`, `middle` and `last` are still supported, but their use is deprecated and they must not be given in combination with the corresponding new style arguments. For persons which are not natural persons (e.g., institutions, companies, etc.) it is appropriate to use `given` (but not `family`) for the name, e.g., `person("R Core Team", role = "aut")`.

The new scheme also adds the possibility of specifying *roles* based on a subset of the MARC Code List for Relators (<https://www.loc.gov/marc/relators/relaterm.html>). When giving the roles of persons in the context of authoring R packages, the following usage is suggested.

`"aut"` (Author) Use for full authors who have made substantial contributions to the package and should show up in the package citation.

`"com"` (Compiler) Use for persons who collected code (potentially in other languages) but did not make further substantial contributions to the package.

`"cph"` (Copyright holder) Use for all copyright holders. This is a legal concept so should use the legal name of an institution or corporate body.

`"cre"` (Creator) Use for the package maintainer.

`"ctb"` (Contributor) Use for authors who have made smaller contributions (such as code patches etc.) but should not show up in the package citation.

`"ctr"` (Contractor) Use for authors who have been contracted to write (parts of) the package and hence do not own intellectual property.

`"dte"` (Data contributor) Use for persons who contributed data sets for the package.

`"fnd"` (Funder) Use for persons or organizations that furnished financial support for the development of the package.

`"rev"` (Reviewer) Use for persons or organizations responsible for reviewing (parts of) the package.

`"ths"` (Thesis advisor) If the package is part of a thesis, use for the thesis advisor.

`"trl"` (Translator) If the R code is a translation from another language (typically S), use for the translator to R.

In the old scheme, person objects were used for single persons, and a separate "personList" class with corresponding creator `personList()` for collections of these. The new scheme employs a single class for information about an arbitrary positive number of persons, eliminating the need for the personList mechanism.

The comment field can be used for "arbitrary" additional information about persons. Elements named "ORCID" will be taken to give ORCID identifiers (see <https://orcid.org/> for more information), and be displayed as the corresponding URIs by the `print()` and `format()` methods (see **Examples** below).

Value

`person()` and `as.person()` return objects of class "person".

Examples

```
## Create a person object directly ...
p1 <- person("Karl", "Pearson", email = "pearson@stats.heaven")

## ... or convert a string.
p2 <- as.person("Ronald Aylmer Fisher")

## Combining and subsetting.
p <- c(p1, p2)
p[1]
p[-1]

## Extracting fields.
p$family
p$email
p[1]$email

## Specifying package authors, example from "boot":
## AC is the first author [aut] who wrote the S original.
## BR is the second author [aut], who translated the code to R [trl],
## and maintains the package [cre].
b <- c(person("Angelo", "Canty", role = "aut", comment =
  "S original, <http://statwww.epfl.ch/davison/BMA/library.html>"),
  person(c("Brian", "D."), "Ripley", role = c("aut", "trl", "cre"),
    comment = "R port", email = "ripley@stats.ox.ac.uk")
  )
b

## Formatting.
format(b)
format(b, include = c("family", "given", "role"),
  braces = list(family = c("", ", "), role = c("(Role(s): ", ")")))

## Conversion to BibTeX author field.
```

```
paste(format(b, include = c("given", "family")), collapse = " and ")
toBibtex(b)

## ORCID identifiers.
(p3 <- person("Achim", "Zeileis",
              comment = c(ORCID = "0000-0003-0918-3766")))
```

personList

Collections of Persons (Older Interface)

Description

Old interface providing functionality for information about collections of persons. Since R 2.14.0 [person](#) objects can be combined with the corresponding `c` method which supersedes the `personList` function.

Usage

```
personList(...)
as.personList(x)
```

Arguments

... person objects (inheriting from class "[person](#)")
 x an object the elements of which are coercible via [as.person](#)

Value

a person object (inheriting from class "[person](#)")

See Also

[person](#) for the new functionality for representing and manipulating information about persons.

PkgUtils

Utilities for Building and Checking Add-on Packages

Description

Utilities for checking whether the sources of an R add-on package work correctly, and for building a source package from them.

Usage

```
R CMD check [options] pkgdirs
R CMD build [options] pkgdirs
```

Arguments

| | |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pkgdirs | a list of names of directories with sources of R add-on packages. For check these can also be the filenames of compressed tar archives with extension <code>‘.tar.gz’</code> , <code>‘.tgz’</code> , <code>‘.tar.bz2’</code> or <code>‘.tar.xz’</code> . |
| options | further options to control the processing, or for obtaining information about usage and version of the utility. |

Details

R CMD check checks R add-on packages from their sources, performing a wide variety of diagnostic checks.

R CMD build builds R source tarballs. The name(s) of the packages are taken from the `‘DESCRIPTION’` files and not from the directory names. This works entirely on a copy of the supplied source directories.

Use R CMD *foo* `--help` to obtain usage information on utility *foo*, notably the possible options.

The defaults for some of the options to R CMD build can be set by environment variables `_R_BUILD_RESAVE_DATA_` and `_R_BUILD_COMPACT_VIGNETTES_`: see `‘Writing R Extensions’`. Many of the checks in R CMD check can be turned off or on by environment variables: see Chapter `‘Tools’` of the `‘R Internals’` manual.

By default R CMD build uses the `“internal”` option to `tar` to prepare the tarball. An external tar program can be specified by the `R_BUILD_TAR` environment variable. This may be substantially faster for very large packages, and can be needed for packages with long path names (over 100 bytes) or very large files (over 8GB): however, the resulting tarball may not be portable.

R CMD check by default unpacks tarballs by the internal `untar` function: if needed an external tar command can be specified by the environment variable `R_INSTALL_TAR`: please ensure that it can handle the type of compression used on the tarball. (This is sometimes needed for tarballs containing invalid or unsupported sections, and can be faster on very large tarballs. Setting `R_INSTALL_TAR` to `‘tar.exe’` has been needed to overcome permissions issues on some Windows systems.)

Note

Only on Windows: They make use of a temporary directory specified by the environment variable `TMPDIR` and defaulting to `‘c:/TEMP’`. Do ensure that if set forward slashes are used.

See Also

The sections on `‘Checking and building packages’` and `‘Processing documentation files’` in `‘Writing R Extensions’`: `RShowDoc(“R-exts”)`.

`process.events`*Trigger Event Handling*

Description

R front ends like the Windows GUI handle key presses and mouse clicks through “events” generated by the OS. These are processed automatically by R at intervals during computations, but in some cases it may be desirable to trigger immediate event handling. The `process.events` function does that.

Usage

```
process.events()
```

Details

This is a simple wrapper for the C API function `R_ProcessEvents`. As such, it is possible that it will not return if the user has signalled to interrupt the calculation.

Value

NULL is returned invisibly.

Author(s)

Duncan Murdoch

See Also

See ‘Writing R Extensions’ and the ‘R for Windows FAQ’ for more discussion of the `R_ProcessEvents` function.

`prompt`*Produce Prototype of an R Documentation File*

Description

Facilitate the constructing of files documenting R objects.

Usage

```
prompt(object, filename = NULL, name = NULL, ...)
```

```
## Default S3 method:
```

```
prompt(object, filename = NULL, name = NULL,
       force.function = FALSE, ...)
```

```
## S3 method for class 'data.frame'
```

```
prompt(object, filename = NULL, name = NULL, ...)
```

```
promptImport(object, filename = NULL, name = NULL,
             importedFrom = NULL, importPage = name, ...)
```

Arguments

| | |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an R object, typically a function for the default method. Can be missing when name is specified. |
| filename | usually, a connection or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is name followed by ".Rd". Can also be NA (see below). |
| name | a character string specifying the name of the object. |
| force.function | a logical. If TRUE, treat object as function in any case. |
| ... | further arguments passed to or from other methods. |
| importedFrom | a character string naming the package from which object was imported. Defaults to the environment of object if object is a function. |
| importPage | a character string naming the help page in the package from which object was imported. |

Details

Unless filename is NA, a documentation shell for object is written to the file specified by filename, and a message about this is given. For function objects, this shell contains the proper function and argument names. R documentation files thus created still need to be edited and moved into the 'man' subdirectory of the package containing the object to be documented.

If filename is NA, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n")`, where x is the list-style representation.

When prompt is used in [for](#) loops or scripts, the explicit name specification will be useful.

The importPage argument for promptImport needs to give the base of the name of the help file of the original help page. For example, the [approx](#) function is documented in 'approxfun.Rd' in the **stats** package, so if it were imported and re-exported it should have importPage = "approxfun". Objects that are imported from other packages are not normally documented unless re-exported.

Value

If filename is NA, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

Warning

The default filename may not be a valid filename under limited file systems (e.g., those on Windows).

Currently, calling `prompt` on a non-function object assumes that the object is in fact a data set and hence documents it as such. This may change in future versions of R. Use `promptData` to create documentation skeletons for data sets.

Note

The documentation file produced by `prompt.data.frame` does not have the same format as many of the data frame documentation files in the **base** package. We are trying to settle on a preferred format for the documentation.

Author(s)

Douglas Bates for `prompt.data.frame`

`promptData`, `help` and the chapter on ‘Writing R documentation files’ in the ‘Writing R Extensions’ manual: `RShowDoc("R-exts")`.

For creation of many help pages (for a package), see `package.skeleton`.

To prompt the user for input, see `readline`.

Examples

```
require(graphics)

prompt(plot.default)
prompt(interactive, force.function = TRUE)
unlink("plot.default.Rd")
unlink("interactive.Rd")

prompt(women) # data.frame
unlink("women.Rd")

prompt(sunspots) # non-data.frame data
unlink("sunspots.Rd")

## Not run:
## Create a help file for each function in the .GlobalEnv:
for(f in ls()) if(is.function(get(f))) prompt(name = f)

## End(Not run)
```

`promptData`*Generate Outline Documentation for a Data Set*

Description

Generates a shell of documentation for a data set.

Usage

```
promptData(object, filename = NULL, name = NULL)
```

Arguments

| | |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an R object to be documented as a data set. |
| <code>filename</code> | usually, a connection or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is <code>name</code> followed by <code>".Rd"</code> . Can also be NA (see below). |
| <code>name</code> | a character string specifying the name of the object. |

Details

Unless `filename` is NA, a documentation shell for `object` is written to the file specified by `filename`, and a message about this is given.

If `filename` is NA, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n")`, where `x` is the list-style representation.

Currently, only data frames are handled explicitly by the code.

Value

If `filename` is NA, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

[prompt](#)

Examples

```
promptData(sunspots)
unlink("sunspots.Rd")
```

promptPackage*Generate a Shell for Documentation of a Package*

Description

Generates a prototype of a package overview help page using Rd macros that dynamically extract information from package metadata when building the package.

Usage

```
promptPackage(package, lib.loc = NULL, filename = NULL,  
              name = NULL, final = FALSE)
```

Arguments

| | |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| package | a character string with the name of the package to be documented. |
| lib.loc | ignored. |
| filename | usually, a connection or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is name followed by ".Rd". Can also be NA (see below). |
| name | a character string specifying the name of the help topic; defaults to "pkgname-package", which is the required <code>\alias</code> for the overview help page. |
| final | a logical value indicating whether to attempt to create a usable version of the help topic, rather than just a shell. |

Details

Unless filename is NA, a documentation shell for package is written to the file specified by filename, and a message about this is given.

If filename is NA, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n")`, where x is the list-style representation.

If final is TRUE, the generated documentation will not include the place-holder slots for manual editing, it will be usable as-is. In most cases a manually edited file is preferable (but final = TRUE is certainly less work).

Value

If filename is NA, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

```
filename <- tempfile()
promptPackage("utils", filename = filename)
file.show(filename)
unlink(filename)
```

Question

Documentation Shortcuts

Description

These functions provide access to documentation. Documentation on a topic with name *name* (typically, an R object or a data set) can be displayed by either `help("name")` or `?name`.

Usage

```
?topic
```

```
type?topic
```

Arguments

| | |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| topic | Usually, a name or character string specifying the topic for which help is sought. Alternatively, a function call to ask for documentation on a corresponding S4 method: see the section on S4 method documentation. The calls <code>pkg::topic</code> and <code>pkg:::topic</code> are treated specially, and look for help on <i>topic</i> in package <i>pkg</i> . |
| type | the special type of documentation to use for this topic; for example, type <code>package</code> will look for the overview help page of a package named <i>topic</i> , and if the type is <code>class</code> , documentation is provided for the S4 class with name <i>topic</i> . See the Section ‘S4 Method Documentation’ for the uses of <i>type</i> to get help on formal methods, including <code>methods?function</code> and <code>method?call</code> . |

Details

This is a shortcut to [help](#) and uses its default type of help.

Some topics need to be quoted (by [backticks](#)) or given as a character string. There include those which cannot syntactically appear on their own such as unary and binary operators, `function` and control-flow [reserved](#) words (including `if`, `else`, `for`, `in`, `repeat`, `while`, `break` and `next`). The other reserved words can be used as if they were names, for example `TRUE`, `NA` and `Inf`.

S4 Method Documentation

Authors of formal ('S4') methods can provide documentation on specific methods, as well as overall documentation on the methods of a particular function. The "?" operator allows access to this documentation in three ways.

The expression `methods?f` will look for the overall documentation methods for the function *f*. Currently, this means the documentation file containing the alias *f*-methods.

There are two different ways to look for documentation on a particular method. The first is to supply the topic argument in the form of a function call, omitting the type argument. The effect is to look for documentation on the method that would be used if this function call were actually evaluated. See the examples below. If the function is not a generic (no S4 methods are defined for it), the help reverts to documentation on the function name.

The "?" operator can also be called with type supplied as method; in this case also, the topic argument is a function call, but the arguments are now interpreted as specifying the class of the argument, not the actual expression that will appear in a real call to the function. See the examples below.

The first approach will be tedious if the actual call involves complicated expressions, and may be slow if the arguments take a long time to evaluate. The second approach avoids these issues, but you do have to know what the classes of the actual arguments will be when they are evaluated.

Both approaches make use of any inherited methods; the signature of the method to be looked up is found by using `selectMethod` (see the documentation for [getMethod](#)). A limitation is that methods in packages (as opposed to regular functions) will only be found if the package exporting them is on the search list, even if it is specified explicitly using the `?package::generic()` notation.

```

rcompgen

A Completion Generator for R

Description

This page documents a mechanism to generate relevant completions from a partially completed command line. It is not intended to be useful by itself, but rather in conjunction with other mechanisms that use it as a backend. The functions listed in the usage section provide a simple control and query mechanism. The actual interface consists of a few unexported functions described further down.

Usage

```

rc.settings(ops, ns, args, dots, func, ipck, S3, data, help,
            argdb, fuzzy, quotes, files, backtick)

rc.status()
rc.getOption(name)
rc.options(...)

.DollarNames(x, pattern)
.AtNames(x, pattern)

## Default S3 method:
.DollarNames(x, pattern = "")
## S3 method for class 'list'
.DollarNames(x, pattern = "")
## S3 method for class 'environment'
.DollarNames(x, pattern = "")

```

```
## Default S3 method:
.AtNames(x, pattern = "")

findMatches(pattern, values, fuzzy, backtick)
```

Arguments

| | |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ops | Logical flag. Activates completion after the \$ and @ operators. |
| ns | Logical flag. Controls namespace related completions. |
| args | Logical flag. Enables completion of function arguments. |
| dots | Logical flag. If disabled, drops ... from list of function arguments. Relevant only if args is enabled. |
| func | Logical flag. Enables detection of functions. If enabled, a customizable extension ("(" by default) is appended to function names. The process of determining whether a potential completion is a function requires evaluation, including for lazy loaded symbols. This is undesirable for large objects, because of potentially wasteful use of memory in addition to the time overhead associated with loading. For this reason, this feature is disabled by default. |
| S3 | Logical flag. When args = TRUE, activates completion on arguments of all S3 methods (otherwise just the generic, which usually has very few arguments). |
| ipck | Logical flag. Enables completion of installed package names inside library and require . |
| data | Logical flag. Enables completion of data sets (including those already visible) inside data . |
| help | Logical flag. Enables completion of help requests starting with a question mark, by looking inside help index files. |
| argdb | Logical flag. When args = TRUE, completion is attempted on function arguments. Generally, the list of valid arguments is determined by dynamic calls to args . While this gives results that are technically correct, the use of the ... argument often hides some useful arguments. To give more flexibility in this regard, an optional table of valid arguments names for specific functions is retained internally. Setting argdb = TRUE enables preferential lookup in this internal data base for functions with an entry in it. Of course, this is useful only when the data base contains information about the function of interest. Some functions are already included, and more can be added by the user through the unexported function <code>.addFunctionInfo</code> (see below). |
| fuzzy | Logical flag. Enables fuzzy matching, where close but non-exact matches (e.g., with different case) are considered if no exact matches are found. This feature is experimental and the details can change. In <code>findMatches</code> , this argument defaults to the current setting. |
| backtick | Logical flag. If enabled, non-syntactic completions are wrapped in backticks to make them syntactically valid. This is useful only if the backend can handle such completions. In <code>findMatches</code> , this argument defaults to the current setting. |

| | |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| quotes | Logical flag. Enables completion in R code when inside quotes. This normally leads to filename completion, but can be otherwise depending on context (for example, when the open quote is preceded by ?), help completion is invoked. Setting this to FALSE relegates completion to the underlying completion front-end, which may do its own processing (for example, readline on Unix-alikes will do filename completion). |
| files | Logical flag. Deprecated. Use quotes instead. |
| name, ... | user-settable options. Currently valid names are function.suffix: default "(" funarg.suffix: default "=" package.suffix: default "::" Usage is similar to that of options . |
| x | An R object for which valid names after "\$" are computed and returned. |
| pattern | A regular expression. Only matching names are returned. |
| values | character string giving set of candidate values in which matches are to be found. |

Details

There are several types of completion, some of which can be disabled using `rc.settings`. The arguments of `rc.settings` are all logical flags, turning specific optional completion features on and off. All settings are on by default except `ipck`, `func`, and `fuzzy`. Turn more off if your CPU cycles are valuable; you will still retain basic completion.

The most basic level, which can not be turned off once the completion functionality is activated, provides completion on names visible on the search path, along with a few special keywords (e.g., `TRUE`). This type of completion is not attempted if the partial ‘word’ (a.k.a. token) being completed is empty (since there would be too many completions). The more advanced types of completion are described below.

Completion after extractors \$ and @: When the `ops` setting is turned on, completion after \$ and @ is attempted. This requires the prefix to be evaluated, which is attempted unless it involves an explicit function call (implicit function calls involving the use of `[`, `$`, etc *do not* inhibit evaluation).

Valid completions after the \$ and @ extractors are determined by the generic functions `.DollarNames` and `.AtNames` respectively. A few basic methods are provided, and more can be written for custom classes. The `findMatches` function can be useful for this purpose.

Completion inside namespaces: When the `ns` setting is turned on, completion inside namespaces is attempted when a token is preceded by the `::` or `:::` operators. Additionally, the basic completion mechanism is extended to include all loaded namespaces, i.e., `foopkg::` becomes a valid completion of `foo` if `"foopkg"` is a loaded namespace.

The completion of package namespaces applies only to already loaded namespaces, i.e. if `MASS` is not loaded, `MAS` will not complete to `MASS::`. However, attempted completion *inside* an apparent namespace will attempt to load the namespace if it is not already loaded, e.g. trying to complete on `MASS::fr` will load `MASS` if it is not already loaded.

Completion for help items: When the `help` setting is turned on, completion on help topics is attempted when a token is preceded by `?`. Prefixes (such as `class`, `method`) are supported, as well as quoted help topics containing special characters.

Completion of function arguments: When the `args` setting is turned on, completion on function arguments is attempted whenever deemed appropriate. The mechanism used will currently fail if the relevant function (at the point where completion is requested) was entered on a previous prompt (which implies in particular that the current line is being typed in response to a continuation prompt, usually `+`). Note that separation by newlines is fine.

The list of possible argument completions that is generated can be misleading. There is no problem for non-generic functions (except that `. . .` is listed as a completion; this is intentional as it signals the fact that the function can accept further arguments). However, for generic functions, it is practically impossible to give a reliable argument list without evaluating arguments (and not even then, in some cases), which is risky (in addition to being difficult to code, which is the real reason it hasn't even been tried), especially when that argument is itself an inline function call. Our compromise is to consider arguments of *all* currently available methods of that generic. This has two drawbacks. First, not all listed completions may be appropriate in the call currently being constructed. Second, for generics with many methods (like `print` and `plot`), many matches will need to be considered, which may take a noticeable amount of time. Despite these drawbacks, we believe this behaviour to be more useful than the only other practical alternative, which is to list arguments of the generic only.

Only S3 methods are currently supported in this fashion, and that can be turned off using the `S3` setting.

Since arguments can be unnamed in R function calls, other types of completion are also appropriate whenever argument completion is. Since there are usually many many more visible objects than formal arguments of any particular function, possible argument completions are often buried in a bunch of other possibilities. However, recall that basic completion is suppressed for blank tokens. This can be useful to list possible arguments of a function. For example, trying to complete `seq([TAB]` and `seq(from = 1, [TAB])` will both list only the arguments of `seq` (or any of its methods), whereas trying to complete `seq(length[TAB]` will list both the `length.out` argument and the `length()` function as possible completions. Note that no attempt is made to remove arguments already supplied, as that would incur a further speed penalty.

Special functions: For a few special functions (`library`, `data`, etc), the first argument is treated specially, in the sense that normal completion is suppressed, and some function specific completions are enabled if so requested by the settings. The `ipck` setting, which controls whether `library` and `require` will complete on *installed packages*, is disabled by default because the first call to `installed.packages` is potentially time consuming (e.g., when packages are installed on a remote network file server). Note, however, that the results of a call to `installed.packages` is cached, so subsequent calls are usually fast, so turning this option on is not particularly onerous even in such situations.

`findMatches` is an utility function that is used internally to determine matches. It can be used for writing methods for `.DollarNames` or `.AtNames`, the main benefit being that it will take the current fuzzy setting into account.

Value

If `rc.settings` is called without any arguments, it returns the current settings as a named logical vector. Otherwise, it returns `NULL` invisibly.

`rc.status` returns, as a list, the contents of an internal (unexported) environment that is used to record the results of the last completion attempt. This can be useful for debugging. For such use,

one must resist the temptation to use completion when typing the call to `rc.status` itself, as that then becomes the last attempt by the time the call is executed.

The items of primary interest in the returned list are:

| | |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>comps</code> | The possible completions generated by the last call to <code>.completeToken</code> , as a character vector. |
| <code>token</code> | The token that was (or, is to be) completed, as set by the last call to <code>.assignToken</code> (possibly inside a call to <code>.guessTokenFromLine</code>). |
| <code>linebuffer</code> | The full line, as set by the last call to <code>.assignLinebuffer</code> . |
| <code>start</code> | The start position of the token in the line buffer, as set by the last call to <code>.assignStart</code> . |
| <code>end</code> | The end position of the token in the line buffer, as set by the last call to <code>.assignEnd</code> . |
| <code>fileName</code> | Logical, indicating whether the cursor is currently inside quotes. |
| <code>fguess</code> | The name of the function the cursor is currently inside. |
| <code>isFirstArg</code> | Logical. If cursor is inside a function, is it the first argument? |

In addition, the components `settings` and `options` give the current values of settings and options respectively.

`rc.getOption` and `rc.options` behave much like `getOption` and `options` respectively.

`findMatches` returns values that match the input pattern, taking the fuzzy flag into account.

Unexported API

There are several unexported functions in the package. Of these, a few are special because they provide the API through which other mechanisms can make use of the facilities provided by this package (they are unexported because they are not meant to be called directly by users). The usage of these functions are:

```
.assignToken(text)
.assignLinebuffer(line)
.assignStart(start)
.assignEnd(end)

.completeToken(custom = TRUE)
.retrieveCompletions()
.getFileComp()

.guessTokenFromLine()
.win32consoleCompletion(linebuffer, cursorPosition,
                        check.repeat = TRUE,
                        minlength = -1)

.addFunctionInfo(...)
```

The first four functions set up a completion attempt by specifying the token to be completed (text), and indicating where (start and end, which should be integers) the token is placed within the complete line typed so far (line).

Potential completions of the token are generated by `.completeToken`, and the completions can be retrieved as an R character vector using `.retrieveCompletions`. It is possible for the user to specify a replacement for this function by setting `rc.options("custom.completer")`; if not NULL, this function is called to compute potential completions. This facility is meant to help in situations where completing as R code is not appropriate. See source code for more details. Custom completion can be disabled by setting `custom = FALSE` when calling `.completeToken`.

If the cursor is inside quotes, completion may be suppressed. The function `.getFileComp` can be used after a call to `.completeToken` to determine if this is the case (returns TRUE), and alternative completions generated as deemed useful. In most cases, filename completion is a reasonable fallback.

The `.guessTokenFromLine` function is provided for use with backends that do not already break a line into tokens. It requires the linebuffer and endpoint (cursor position) to be already set, and itself sets the token and the start position. It returns the token as a character string.

The `.win32consoleCompletion` is similar in spirit, but is more geared towards the Windows GUI (or rather, any front-end that has no completion facilities of its own). It requires the linebuffer and cursor position as arguments, and returns a list with three components, `addition`, `possible` and `comps`. If there is an unambiguous extension at the current position, `addition` contains the additional text that should be inserted at the cursor. If there is more than one possibility, these are available either as a character vector of preformatted strings in `possible`, or as a single string in `comps`. `possible` consists of lines formatted using the current width option, so that printing them on the console one line at a time will be a reasonable way to list them. `comps` is a space separated (collapsed) list of the same completions, in case the front-end wishes to display it in some other fashion.

The `minlength` argument can be used to suppress completion when the token is too short (which can be useful if the front-end is set up to try completion on every keypress). If `check.repeat` is TRUE, it is detected if the same completion is being requested more than once in a row, and ambiguous completions are returned only in that case. This is an attempt to emulate GNU Readline behaviour, where a single TAB completes up to any unambiguous part, and multiple possibilities are reported only on two consecutive TABs.

As the various front-end interfaces evolve, the details of these functions are likely to change as well.

The function `.addFunctionInfo` can be used to add information about the permitted argument names for specific functions. Multiple named arguments are allowed in calls to it, where the tags are names of functions and values are character vectors representing valid arguments. When the `argdb` setting is TRUE, these are used as a source of valid argument names for the relevant functions.

Note

If you are uncomfortable with unsolicited evaluation of pieces of code, you should set `ops = FALSE`. Otherwise, trying to complete `foo@ba` will evaluate `foo`, trying to complete `foo[i, 1:10]$ba` will evaluate `foo[i, 1:10]`, etc. This should not be too bad, as explicit function calls (involving parentheses) are not evaluated in this manner. However, this *will* affect promises and lazy loaded symbols.

Author(s)

read.DIF

Data Input from Spreadsheet

Description

Reads a file in Data Interchange Format (DIF) and creates a data frame from it. DIF is a format for data matrices such as single spreadsheets.

Usage

```
read.DIF(file, header = FALSE,
         dec = ".", numerals = c("allow.loss", "warn.loss", "no.loss"),
         row.names, col.names, as.is = !stringsAsFactors,
         na.strings = "NA", colClasses = NA, nrow = -1,
         skip = 0, check.names = TRUE, blank.lines.skip = TRUE,
         stringsAsFactors = FALSE,
         transpose = FALSE, fileEncoding = "")
```

Arguments

- | | |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| file | the name of the file which the data are to be read from, or a connection , or a complete URL. The name "clipboard" may also be used on Windows, in which case read.DIF("clipboard") will look for a DIF format entry in the Windows clipboard. |
| header | a logical value indicating whether the spreadsheet contains the names of the variables as its first line. If missing, the value is determined from the file format: header is set to TRUE if and only if the first row contains only character values and the top left cell is empty. |
| dec | the character used in the file for decimal points. |
| numerals | string indicating how to convert numbers whose conversion to double precision would lose accuracy, see type.convert . |
| row.names | a vector of row names. This can be a vector giving the actual row names, or a single number giving the column of the table which contains the row names, or character string giving the name of the table column containing the row names. If there is a header and the first row contains one fewer field than the number of columns, the first column in the input is used for the row names. Otherwise if row.names is missing, the rows are numbered. Using row.names = NULL forces row numbering. |
| col.names | a vector of optional names for the variables. The default is to use "V" followed by the column number. |

| | |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| as.is | controls conversion of character variables (insofar as they are not converted to logical, numeric or complex) to factors, if not otherwise specified by colClasses. Its value is either a vector of logicals (values are recycled if necessary), or a vector of numeric or character indices which specify which columns should not be converted to factors. Note: In releases prior to R 2.12.1, cells marked as being of character type were converted to logical, numeric or complex using type.convert as in read.table . Note: to suppress all conversions including those of numeric columns, set colClasses = "character". Note that as.is is specified per column (not per variable) and so includes the column of row names (if any) and any columns to be skipped. |
| na.strings | a character vector of strings which are to be interpreted as NA values. Blank fields are also considered to be missing values in logical, integer, numeric and complex fields. |
| colClasses | character. A vector of classes to be assumed for the columns. Recycled as necessary, or if the character vector is named, unspecified values are taken to be NA. Possible values are NA (when type.convert is used), "NULL" (when the column is skipped), one of the atomic vector classes (logical, integer, numeric, complex, character, raw), or "factor", "Date" or "POSIXct". Otherwise there needs to be an as method (from package methods) for conversion from "character" to the specified formal class. Note that colClasses is specified per column (not per variable) and so includes the column of row names (if any). |
| nrows | the maximum number of rows to read in. Negative values are ignored. |
| skip | the number of lines of the data file to skip before beginning to read data. |
| check.names | logical. If TRUE then the names of the variables in the data frame are checked to ensure that they are syntactically valid variable names. If necessary they are adjusted (by make.names) so that they are, and also to ensure that there are no duplicates. |
| blank.lines.skip | logical: if TRUE blank lines in the input are ignored. |
| stringsAsFactors | logical: should character vectors be converted to factors? |
| transpose | logical, indicating if the row and column interpretation should be transposed. Microsoft's Excel has been known to produce (non-standard conforming) DIF files which would need transpose = TRUE to be read correctly. |
| fileEncoding | character string: if non-empty declares the encoding used on a file (not a connection or clipboard) so the character data can be re-encoded. See the 'Encoding' section of the help for file , the 'R Data Import/Export' manual and 'Note'. |

Value

A data frame ([data.frame](#)) containing a representation of the data in the file. Empty input is an error unless col.names is specified, when a 0-row data frame is returned: similarly giving just a header line if header = TRUE results in a 0-row data frame.

Note

The columns referred to in `as.is` and `colClasses` include the column of row names (if any).
 Less memory will be used if `colClasses` is specified as one of the six atomic vector classes.

Author(s)

R Core; transpose option by Christoph Buser, ETH Zurich

References

The DIF format specification can be found by searching on <http://www.wotsit.org/>; the optional header fields are ignored. See also https://en.wikipedia.org/wiki/Data_Interchange_Format.

The term is likely to lead to confusion: Windows will have a ‘Windows Data Interchange Format (DIF) data format’ as part of its WinFX system, which may or may not be compatible.

The *R Data Import/Export* manual.

`scan`, `type.convert`, `read.fwf` for reading fixed width formatted input; `read.table`; `data.frame`.

Examples

```
## read.DIF() may need transpose = TRUE for a file exported from Excel
udir <- system.file("misc", package = "utils")
dd <- read.DIF(file.path(udir, "exDIF.dif"), header = TRUE, transpose = TRUE)
dc <- read.csv(file.path(udir, "exDIF.csv"), header = TRUE)
stopifnot(identical(dd, dc), dim(dd) == c(4,2))
```

read.fortran

Read Fixed-Format Data in a Fortran-like Style

Description

Read fixed-format data files using Fortran-style format specifications.

Usage

```
read.fortran(file, format, ..., as.is = TRUE, colClasses = NA)
```

Arguments

| | |
|-------------------------|------------------------------------------------------------------------------------|
| <code>file</code> | File or connection to read from. |
| <code>format</code> | Character vector or list of vectors. See ‘Details’ below. |
| <code>...</code> | Other arguments for read.fwf . |
| <code>as.is</code> | Keep characters as characters? |
| <code>colClasses</code> | Variable classes to override defaults. See read.table for details. |

Details

The format for a field is of one of the following forms: `rF1.d`, `rD1.d`, `rX1`, `rA1`, `rI1`, where `1` is the number of columns, `d` is the number of decimal places, and `r` is the number of repeats. `F` and `D` are numeric formats, `A` is character, `I` is integer, and `X` indicates columns to be skipped. The repeat code `r` and decimal place code `d` are always optional. The length code `1` is required except for `X` formats when `r` is present.

For a single-line record, format should be a character vector. For a multiline record it should be a list with a character vector for each line.

Skipped (`X`) columns are not passed to `read.fwf`, so `colClasses`, `col.names`, and similar arguments passed to `read.fwf` should not reference these columns.

Value

A data frame

Note

`read.fortran` does not use actual Fortran input routines, so the formats are at best rough approximations to the Fortran ones. In particular, specifying `d > 0` in the `F` or `D` format will shift the decimal `d` places to the left, even if it is explicitly specified in the input file.

See Also

[read.fwf](#), [read.table](#), [read.csv](#)

Examples

```
ff <- tempfile()
cat(file = ff, "123456", "987654", sep = "\n")
read.fortran(ff, c("F2.1", "F2.0", "I2"))
read.fortran(ff, c("2F1.0", "2X", "2A1"))
unlink(ff)
cat(file = ff, "123456AB", "987654CD", sep = "\n")
read.fortran(ff, list(c("2F3.1", "A2"), c("3I2", "2X")))
unlink(ff)
# Note that the first number is read differently than Fortran would
# read it:
cat(file = ff, "12.3456", "1234567", sep = "\n")
read.fortran(ff, "F7.4")
unlink(ff)
```

read.fwf

Read Fixed Width Format Files

Description

Read a table of fixed width formatted data into a [data.frame](#).

Usage

```
read.fwf(file, widths, header = FALSE, sep = "\t",
         skip = 0, row.names, col.names, n = -1,
         buffersize = 2000, fileEncoding = "", ...)
```

Arguments

| | |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>file</code> | the name of the file which the data are to be read from. Alternatively, <code>file</code> can be a connection , which will be opened if necessary, and if so closed at the end of the function call. |
| <code>widths</code> | integer vector, giving the widths of the fixed-width fields (of one line), or list of integer vectors giving widths for multiline records. |
| <code>header</code> | a logical value indicating whether the file contains the names of the variables as its first line. If present, the names must be delimited by <code>sep</code> . |
| <code>sep</code> | character; the separator used internally; should be a character that does not occur in the file (except in the header). |
| <code>skip</code> | number of initial lines to skip; see read.table . |
| <code>row.names</code> | see read.table . |
| <code>col.names</code> | see read.table . |
| <code>n</code> | the maximum number of records (lines) to be read, defaulting to no limit. |
| <code>buffersize</code> | Maximum number of lines to read at one time |
| <code>fileEncoding</code> | character string: if non-empty declares the encoding used on a file (not a connection) so the character data can be re-encoded. See the ‘Encoding’ section of the help for file , the ‘R Data Import/Export’ manual and ‘Note’. |
| <code>...</code> | further arguments to be passed to read.table . Useful such arguments include <code>as.is</code> , <code>na.strings</code> , <code>colClasses</code> and <code>strip.white</code> . |

Details

Multiline records are concatenated to a single line before processing. Fields that are of zero-width or are wholly beyond the end of the line in `file` are replaced by NA.

Negative-width fields are used to indicate columns to be skipped, e.g., -5 to skip 5 columns. These fields are not seen by `read.table` and so should not be included in a `col.names` or `colClasses` argument (nor in the header line, if present).

Reducing the `buffersize` argument may reduce memory use when reading large files with long lines. Increasing `buffersize` may result in faster processing when enough memory is available.

Note that `read.fwf` (not `read.table`) reads the supplied file, so the latter’s argument `encoding` will not be useful.

Value

A [data.frame](#) as produced by [read.table](#) which is called internally.

Author(s)

Brian Ripley for R version: originally in Perl by Kurt Hornik.

See Also

[scan](#) and [read.table](#).

[read.fortran](#) for another style of fixed-format files.

Examples

```
ff <- tempfile()
cat(file = ff, "123456", "987654", sep = "\n")
read.fwf(ff, widths = c(1,2,3))    #> 1 23 456 \ 9 87 654
read.fwf(ff, widths = c(1,-2,3))   #> 1 456 \ 9 654
unlink(ff)
cat(file = ff, "123", "987654", sep = "\n")
read.fwf(ff, widths = c(1,0, 2,3))  #> 1 NA 23 NA \ 9 NA 87 654
unlink(ff)
cat(file = ff, "123456", "987654", sep = "\n")
read.fwf(ff, widths = list(c(1,0, 2,3), c(2,2,2))) #> 1 NA 23 456 98 76 54
unlink(ff)
```

read.socket

Read from or Write to a Socket

Description

`read.socket` reads a string from the specified socket, `write.socket` writes to the specified socket. There is very little error checking done by either.

Usage

```
read.socket(socket, maxlen = 256L, loop = FALSE)
write.socket(socket, string)
```

Arguments

| | |
|--------|----------------------------------------------|
| socket | a socket object. |
| maxlen | maximum length (in bytes) of string to read. |
| loop | wait for ever if there is nothing to read? |
| string | string to write to socket. |

Value

`read.socket` returns the string read as a length-one character vector.
`write.socket` returns the number of bytes written.

Author(s)

Thomas Lumley

See Also[close.socket](#), [make.socket](#)**Examples**

```

finger <- function(user, host = "localhost", port = 79, print = TRUE)
{
  if (!is.character(user))
    stop("user name must be a string")
  user <- paste(user, "\r\n")
  socket <- make.socket(host, port)
  on.exit(close.socket(socket))
  write.socket(socket, user)
  output <- character(0)
  repeat{
    ss <- read.socket(socket)
    if (ss == "") break
    output <- paste(output, ss)
  }
  close.socket(socket)
  if (print) cat(output)
  invisible(output)
}
## Not run:
finger("root") ## only works if your site provides a finger daemon
## End(Not run)

```

read.table

*Data Input***Description**

Reads a file in table format and creates a data frame from it, with cases corresponding to lines and variables to fields in the file.

Usage

```

read.table(file, header = FALSE, sep = "", quote = "\"'",
  dec = ".", numerals = c("allow.loss", "warn.loss", "no.loss"),
  row.names, col.names, as.is = !stringsAsFactors, tryLogical = TRUE,
  na.strings = "NA", colClasses = NA, nrows = -1,
  skip = 0, check.names = TRUE, fill = !blank.lines.skip,
  strip.white = FALSE, blank.lines.skip = TRUE,
  comment.char = "#",
  allowEscapes = FALSE, flush = FALSE,

```

```

stringsAsFactors = FALSE,
fileEncoding = "", encoding = "unknown", text, skipNul = FALSE)

read.csv(file, header = TRUE, sep = ",", quote = "\"",
         dec = ".", fill = TRUE, comment.char = "", ...)

read.csv2(file, header = TRUE, sep = ";", quote = "\"",
          dec = ",", fill = TRUE, comment.char = "", ...)

read.delim(file, header = TRUE, sep = "\t", quote = "\"",
           dec = ".", fill = TRUE, comment.char = "", ...)

read.delim2(file, header = TRUE, sep = "\t", quote = "\"",
            dec = ",", fill = TRUE, comment.char = "", ...)

```

Arguments

| | |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| file | <p>the name of the file which the data are to be read from. Each row of the table appears as one line of the file. If it does not contain an <i>absolute</i> path, the file name is <i>relative</i> to the current working directory, <code>getwd()</code>. Tilde-expansion is performed where supported. This can be a compressed file (see file).</p> <p>Alternatively, file can be a readable text-mode connection (which will be opened for reading if necessary, and if so closed (and hence destroyed) at the end of the function call). (If <code>stdin()</code> is used, the prompts for lines may be somewhat confusing. Terminate input with a blank line or an EOF signal, Ctrl-D on Unix and Ctrl-Z on Windows. Any pushback on <code>stdin()</code> will be cleared before return.)</p> <p>file can also be a complete URL. (For the supported URL schemes, see the ‘URLs’ section of the help for url.)</p> |
| header | a logical value indicating whether the file contains the names of the variables as its first line. If missing, the value is determined from the file format: header is set to TRUE if and only if the first row contains one fewer field than the number of columns. |
| sep | the field separator character. Values on each line of the file are separated by this character. If <code>sep = ""</code> (the default for <code>read.table</code>) the separator is ‘white space’, that is one or more spaces, tabs, newlines or carriage returns. |
| quote | the set of quoting characters. To disable quoting altogether, use <code>quote = ""</code> . See scan for the behaviour on quotes embedded in quotes. Quoting is only considered for columns read as character, which is all of them unless <code>colClasses</code> is specified. |
| dec | the character used in the file for decimal points. |
| numerals | string indicating how to convert numbers whose conversion to double precision would lose accuracy, see type.convert . Can be abbreviated. (Applies also to complex-number inputs.) |
| row.names | a vector of row names. This can be a vector giving the actual row names, or a single number giving the column of the table which contains the row names, or character string giving the name of the table column containing the row names. |

| | |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| | <p>If there is a header and the first row contains one fewer field than the number of columns, the first column in the input is used for the row names. Otherwise if row.names is missing, the rows are numbered.</p> <p>Using row.names = NULL forces row numbering. Missing or NULL row.names generate row names that are considered to be ‘automatic’ (and not preserved by as.matrix).</p> |
| col.names | a vector of optional names for the variables. The default is to use "V" followed by the column number. |
| as.is | <p>controls conversion of character variables (insofar as they are not converted to logical, numeric or complex) to factors, if not otherwise specified by colClasses. Its value is either a vector of logicals (values are recycled if necessary), or a vector of numeric or character indices which specify which columns should not be converted to factors.</p> <p>Note: to suppress all conversions including those of numeric columns, set colClasses = "character".</p> <p>Note that as.is is specified per column (not per variable) and so includes the column of row names (if any) and any columns to be skipped.</p> |
| tryLogical | a logical determining if columns consisting entirely of "F", "T", "FALSE", and "TRUE" should be converted to logical ; passed to type.convert , true by default. |
| na.strings | a character vector of strings which are to be interpreted as NA values. Blank fields are also considered to be missing values in logical, integer, numeric and complex fields. Note that the test happens <i>after</i> white space is stripped from the input (if enabled), so na.strings values may need their own white space stripped in advance. |
| colClasses | <p>character. A vector of classes to be assumed for the columns. If unnamed, recycled as necessary. If named, names are matched with unspecified values being taken to be NA.</p> <p>Possible values are NA (the default, when type.convert is used), "NULL" (when the column is skipped), one of the atomic vector classes (logical, integer, numeric, complex, character, raw), or "factor", "Date" or "POSIXct". Otherwise there needs to be an as method (from package methods) for conversion from "character" to the specified formal class.</p> <p>Note that colClasses is specified per column (not per variable) and so includes the column of row names (if any).</p> |
| nrows | integer: the maximum number of rows to read in. Negative and other invalid values are ignored. |
| skip | integer: the number of lines of the data file to skip before beginning to read data. |
| check.names | logical. If TRUE then the names of the variables in the data frame are checked to ensure that they are syntactically valid variable names. If necessary they are adjusted (by make.names) so that they are, and also to ensure that there are no duplicates. |
| fill | logical. If TRUE then in case the rows have unequal length, blank fields are implicitly added. See ‘Details’. |

| | |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>strip.white</code> | logical. Used only when <code>sep</code> has been specified, and allows the stripping of leading and trailing white space from unquoted character fields (numeric fields are always stripped). See scan for further details (including the exact meaning of ‘white space’), remembering that the columns may include the row names. |
| <code>blank.lines.skip</code> | logical: if TRUE blank lines in the input are ignored. |
| <code>comment.char</code> | character: a character vector of length one containing a single character or an empty string. Use "" to turn off the interpretation of comments altogether. |
| <code>allowEscapes</code> | logical. Should C-style escapes such as ‘\n’ be processed or read verbatim (the default)? Note that if not within quotes these could be interpreted as a delimiter (but not as a comment character). For more details see scan . |
| <code>flush</code> | logical: if TRUE, <code>scan</code> will flush to the end of the line after reading the last of the fields requested. This allows putting comments after the last field. |
| <code>stringsAsFactors</code> | logical: should character vectors be converted to factors? Note that this is overridden by <code>as.is</code> and <code>colClasses</code> , both of which allow finer control. |
| <code>fileEncoding</code> | character string: if non-empty declares the encoding used on a file when given as a character string (not on an existing connection) so the character data can be re-encoded. See the ‘Encoding’ section of the help for file , the ‘R Data Import/Export’ manual and ‘Note’. |
| <code>encoding</code> | encoding to be assumed for input strings. It is used to mark character strings as known to be in Latin-1 or UTF-8 (see Encoding): it is not used to re-encode the input, but allows R to handle encoded strings in their native encoding (if one of those two). See ‘Value’ and ‘Note’. |
| <code>text</code> | character string: if <code>file</code> is not supplied and this is, then data are read from the value of <code>text</code> via a text connection. Notice that a literal string can be used to include (small) data sets within R code. |
| <code>skipNul</code> | logical: should NULs be skipped? |
| <code>...</code> | Further arguments to be passed to <code>read.table</code> . |

Details

This function is the principal means of reading tabular data into R.

Unless `colClasses` is specified, all columns are read as character columns and then converted using [type.convert](#) to logical, integer, numeric, complex or (depending on `as.is`) factor as appropriate. Quotes are (by default) interpreted in all fields, so a column of values like "42" will result in an integer column.

A field or line is ‘blank’ if it contains nothing (except whitespace if no separator is specified) before a comment character or the end of the field or line.

If `row.names` is not specified and the header line has one less entry than the number of columns, the first column is taken to be the row names. This allows data frames to be read in from the format in which they are printed. If `row.names` is specified and does not refer to the first column, that column is discarded from such files.

The number of data columns is determined by looking at the first five lines of input (or the whole input if it has less than five lines), or from the length of `col.names` if it is specified and is longer.

This could conceivably be wrong if `fill` or `blank.lines.skip` are true, so specify `col.names` if necessary (as in the ‘Examples’).

`read.csv` and `read.csv2` are identical to `read.table` except for the defaults. They are intended for reading ‘comma separated value’ files (‘.csv’) or (`read.csv2`) the variant used in countries that use a comma as decimal point and a semicolon as field separator. Similarly, `read.delim` and `read.delim2` are for reading delimited files, defaulting to the TAB character for the delimiter. Notice that `header = TRUE` and `fill = TRUE` in these variants, and that the comment character is disabled.

The rest of the line after a comment character is skipped; quotes are not processed in comments. Complete comment lines are allowed provided `blank.lines.skip = TRUE`; however, comment lines prior to the header must have the comment character in the first non-blank column.

Quoted fields with embedded newlines are supported except after a comment character. Embedded NULs are unsupported: skipping them (with `skipNul = TRUE`) may work.

Value

A data frame ([data.frame](#)) containing a representation of the data in the file.

Empty input is an error unless `col.names` is specified, when a 0-row data frame is returned: similarly giving just a header line if `header = TRUE` results in a 0-row data frame. Note that in either case the columns will be logical unless `colClasses` was supplied.

Character strings in the result (including factor levels) will have a declared encoding if `encoding` is “latin1” or “UTF-8”.

CSV files

See the help on [write.csv](#) for the various conventions for .csv files. The commonest form of CSV file with row names needs to be read with `read.csv(..., row.names = 1)` to use the names in the first column of the file as row names.

Memory usage

These functions can use a surprising amount of memory when reading large files. There is extensive discussion in the ‘R Data Import/Export’ manual, supplementing the notes here.

Less memory will be used if `colClasses` is specified as one of the six [atomic](#) vector classes. This can be particularly so when reading a column that takes many distinct numeric values, as storing each distinct value as a character string can take up to 14 times as much memory as storing it as an integer.

Using `nrows`, even as a mild over-estimate, will help memory usage.

Using `comment.char = ""` will be appreciably faster than the `read.table` default.

`read.table` is not the right tool for reading large matrices, especially those with many columns: it is designed to read *data frames* which may have columns of very different classes. Use [scan](#) instead for matrices.

Note

The columns referred to in `as.is` and `colClasses` include the column of row names (if any).

There are two approaches for reading input that is not in the local encoding. If the input is known to be UTF-8 or Latin1, use the `encoding` argument to declare that. If the input is in some other encoding, then it may be translated on input. The `fileEncoding` argument achieves this by setting up a connection to do the re-encoding into the current locale. Note that on Windows or other systems not running in a UTF-8 locale, this may not be possible.

See Also

The ‘R Data Import/Export’ manual.

`scan`, `type.convert`, `read.fwf` for reading *fixed width formatted* input; `write.table`; `data.frame`.

`count.fields` can be useful to determine problems with reading files which result in reports of incorrect record lengths (see the ‘Examples’ below).

<https://www.rfc-editor.org/rfc/rfc4180> for the IANA definition of CSV files (which requires comma as separator and CRLF line endings).

Examples

```
## using count.fields to handle unknown maximum number of fields
## when fill = TRUE
test1 <- c(1:5, "6,7", "8,9,10")
tf <- tempfile()
writeLines(test1, tf)

read.csv(tf, fill = TRUE) # 1 column
ncol <- max(count.fields(tf, sep = ","))
read.csv(tf, fill = TRUE, header = FALSE,
         col.names = paste0("V", seq_len(ncol)))
unlink(tf)

## "Inline" data set, using text=
## Notice that leading and trailing empty lines are auto-trimmed

read.table(header = TRUE, text = "
a b
1 2
3 4
")
```

| | |
|--------------|-------------------------------------|
| readRegistry | <i>Read a Windows Registry Hive</i> |
|--------------|-------------------------------------|

Description

On Windows, read values of keys in the Windows Registry, and optionally whole hives.

Usage

```
readRegistry(key, hive = c("HLM", "HCR", "HCU", "HU", "HCC", "HPD"),
             maxdepth = 1, view = c("default", "32-bit", "64-bit"))
```

Arguments

| | |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| key | character string, the path to the key in the Windows Registry. |
| hive | The 'hive' containing the key. The abbreviations are for HKEY_LOCAL_MACHINE, HKEY_CLASSES_ROOT, HKEY_CURRENT_USER, HKEY_USERS, HKEY_CURRENT_CONFIG and HKEY_PERFORMANCE_DATA |
| maxdepth | How far to recurse into the subkeys of the key. By default only the values of the key and the names of subkeys are returned. |
| view | On 64-bit Windows, the view of the Registry to be used: see 'Details'. |

Details

Registry access is done using the security settings of the current R session: this means that some Registry keys may not be accessible even if they exist. This may result in NULL values in the object returned, and, possibly, empty element names.

On 64-bit Windows, this will by default read the 32-bit view of the Registry when run from 32-bit R, and the 64-bit view when run from 64-bit R: see <https://learn.microsoft.com/en-us/windows/win32/winprog64/registry-redirector>.

Value

A named list of values and subkeys (which may themselves be named lists). The default value (if any) precedes named values which precede subkeys, and both the latter sets are sorted alphabetically.

Note

This is only available on Windows.

Examples

```
if(.Platform$OS.type == "windows") withAutoprint({
  ## only in HLM if set in an admin-mode install.
  try(readRegistry("SOFTWARE\\R-core", maxdepth = 3))

  gmt <- file.path("SOFTWARE", "Microsoft", "Windows NT",
    "CurrentVersion", "Time Zones",
    "GMT Standard Time", fsep = "\\")
  readRegistry(gmt, "HLM")
})
## Not run: ## on a 64-bit R need this to find 32-bit JAGS
readRegistry("SOFTWARE\\JAGS", maxdepth = 3, view = "32")

## See if there is a 64-bit user install
readRegistry("SOFTWARE\\R-core\\R64", "HCU", maxdepth = 2)

## End(Not run)
```

recover

Browsing after an Error

Description

This function allows the user to browse directly on any of the currently active function calls, and is suitable as an error option. The expression `options(error = recover)` will make this the error option.

Usage

```
recover()
```

Details

When called, `recover` prints the list of current calls, and prompts the user to select one of them. The standard R [browser](#) is then invoked from the corresponding environment; the user can type ordinary R language expressions to be evaluated in that environment.

When finished browsing in this call, type `c` to return to `recover` from the browser. Type another frame number to browse some more, or type `0` to exit `recover`.

The use of `recover` largely supersedes [dump.frames](#) as an error option, unless you really want to wait to look at the error. If `recover` is called in non-interactive mode, it behaves like `dump.frames`. For computations involving large amounts of data, `recover` has the advantage that it does not need to copy out all the environments in order to browse in them. If you do decide to quit interactive debugging, call [dump.frames](#) directly while browsing in any frame (see the examples).

Value

Nothing useful is returned. However, you *can* invoke `recover` directly from a function, rather than through the error option shown in the examples. In this case, execution continues after you type `0` to exit `recover`.

Compatibility Note

The R recover function can be used in the same way as the S function of the same name; therefore, the error option shown is a compatible way to specify the error action. However, the actual functions are essentially unrelated and interact quite differently with the user. The navigating commands up and down do not exist in the R version; instead, exit the browser and select another frame.

References

John M. Chambers (1998). *Programming with Data*; Springer.
See the compatibility note above, however.

See Also

[browser](#) for details about the interactive computations; [options](#) for setting the error option; [dump.frames](#) to save the current environments for later debugging.

Examples

```
## Not run:

options(error = recover) # setting the error option

### Example of interaction

> myFit <- lm(y ~ x, data = xy, weights = w)
Error in lm.wfit(x, y, w, offset = offset, ...) :
  missing or negative weights not allowed

Enter a frame number, or 0 to exit
1:lm(y ~ x, data = xy, weights = w)

## End(Not run)
```

relist

*Allow Re-Listing an unlist()ed Object***Description**

`relist()` is an S3 generic function with a few methods in order to allow easy inversion of `unlist(obj)` when that is used with an object `obj` of (S3) class "relistable".

Usage

```
relist(flesh, skeleton)
## Default S3 method:
relist(flesh, skeleton = attr(flesh, "skeleton"))
## S3 method for class 'factor'
relist(flesh, skeleton = attr(flesh, "skeleton"))
## S3 method for class 'list'
relist(flesh, skeleton = attr(flesh, "skeleton"))
## S3 method for class 'matrix'
relist(flesh, skeleton = attr(flesh, "skeleton"))

as.relistable(x)
is.relistable(x)

## S3 method for class 'relistable'
unlist(x, recursive = TRUE, use.names = TRUE)
```

Arguments

| | |
|------------------------|-----------------------------------------------------------------------------|
| <code>flesh</code> | a vector to be relisted |
| <code>skeleton</code> | a list, the structure of which determines the structure of the result |
| <code>x</code> | an R object, typically a list (or vector). |
| <code>recursive</code> | logical. Should unlisting be applied to list components of <code>x</code> ? |
| <code>use.names</code> | logical. Should names be preserved? |

Details

Some functions need many parameters, which are most easily represented in complex structures, e.g., nested lists. Unfortunately, many mathematical functions in R, including `optim` and `nlm` can only operate on functions whose domain is a vector. R has `unlist()` to convert nested list objects into a vector representation. `relist()`, its methods and the functionality mentioned here provide the inverse operation to convert vectors back to the convenient structural representation. This allows structured functions (such as `optim()`) to have simple mathematical interfaces.

For example, a likelihood function for a multivariate normal model needs a variance-covariance matrix and a mean vector. It would be most convenient to represent it as a list containing a vector and a matrix. A typical parameter might look like

```
list(mean = c(0, 1), vcov = cbind(c(1, 1), c(1, 0))).
```

However, `optim` cannot operate on functions that take lists as input; it only likes numeric vectors. The solution is conversion. Given a function `mvdnorm(x, mean, vcov, log = FALSE)` which computes the required probability density, then

```
ipar <- list(mean = c(0, 1), vcov = cbind(c(1, 1), c(1, 0)))
initial.param <- as.relistable(ipar)

ll <- function(param.vector)
{
  param <- relist(param.vector, skeleton = ipar)
  -sum(mvdnorm(x, mean = param$mean, vcov = param$vcov,
              log = TRUE))
}

optim(unlist(initial.param), ll)
```

`relist` takes two parameters: `skeleton` and `flesh`. `Skeleton` is a sample object that has the right shape but the wrong content. `flesh` is a vector with the right content but the wrong shape. Invoking

```
relist(flesh, skeleton)
```

will put the content of `flesh` on the `skeleton`. You don't need to specify `skeleton` explicitly if the `skeleton` is stored as an attribute inside `flesh`. In particular, if `flesh` was created from some object `obj` with `unlist(as.relistable(obj))` then the `skeleton` attribute is automatically set. (Note that this does not apply to the example here, as `optim` is creating a new vector to pass to `ll` and not its `par` argument.)

As long as `skeleton` has the right shape, it should be an inverse of `unlist`. These equalities hold:

```
relist(unlist(x), x) == x
unlist(relist(y, skeleton)) == y

x <- as.relistable(x)
relist(unlist(x)) == x
```

Note however that the relisted object might not be *identical* to the `skeleton` because of implicit coercions performed during the unlisting step. All elements of the relisted objects have the same type as the unlisted object. `NULL` values are coerced to empty vectors of that type.

Value

an object of (S3) class `"relistable"` (and `"list"`).

Author(s)

R Core, based on a code proposal by Andrew Clausen.

See Also[unlist](#)**Examples**

```
ipar <- list(mean = c(0, 1), vcov = cbind(c(1, 1), c(1, 0)))
initial.param <- as.relistable(ipar)
ul <- unlist(initial.param)
relist(ul)
stopifnot(identical(relist(ul), initial.param))
```

REMOVE

*Remove Add-on Packages***Description**

Utility for removing add-on packages.

Usage

```
R CMD REMOVE [options] [-l lib] pkgs
```

Arguments

| | |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pkgs</code> | a space-separated list with the names of the packages to be removed. |
| <code>lib</code> | the path name of the R library tree to remove from. May be absolute or relative. Also accepted in the form ‘ <code>--library=lib</code> ’. |
| <code>options</code> | further options for help or version. |

Details

If used as `R CMD REMOVE pkgs` without explicitly specifying `lib`, packages are removed from the library tree rooted at the first directory in the library path which would be used by R run in the current environment.

To remove from the library tree *lib* instead of the default one, use `R CMD REMOVE -l lib pkgs`.

Use `R CMD REMOVE --help` for more usage information.

Note

Some binary distributions of R have REMOVE in a separate bundle, e.g. an R-devel RPM.

See Also

[INSTALL](#), [remove.packages](#)

| | |
|-----------------|----------------------------------|
| remove.packages | <i>Remove Installed Packages</i> |
|-----------------|----------------------------------|

Description

Removes installed packages/bundles and updates index information as necessary.

Usage

```
remove.packages(pkgs, lib)
```

Arguments

| | |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| pkgs | a character vector with the names of the packages to be removed. |
| lib | a character vector giving the library directories to remove the packages from. If missing, defaults to the first element in <code>.libPaths()</code> . |

See Also

On Unix-alikes, [REMOVE](#) for a command line version;
[install.packages](#) for installing packages.

| | |
|--------------|----------------------------------------------------------------|
| removeSource | <i>Remove Stored Source from a Function or Language Object</i> |
|--------------|----------------------------------------------------------------|

Description

When `options("keep.source")` is TRUE, a copy of the original source code to a function is stored with it. Similarly, [parse\(\)](#) may keep formatted source for an expression. Such source reference attributes are removed from the object by `removeSource()`.

Usage

```
removeSource(fn)
```

Arguments

| | |
|----|----------------------------------------------------------------------------------------------------------------------------------|
| fn | a function or another language object (fulfilling is.language) from which to remove the source. |
|----|----------------------------------------------------------------------------------------------------------------------------------|

Details

This removes the "srcref" and related attributes, via *recursive* cleaning of `body(fn)` in the case of a function or the recursive language parts, otherwise.

Value

A copy of the fn object with the source removed.

See Also

[is.language](#) about language objects.

[srcref](#) for a description of source reference records, [deparse](#) for a description of how functions are deparsed.

Examples

```
## to make this act independently of the global 'options()' setting:
op <- options(keep.source = TRUE)
fn <- function(x) {
  x + 1 # A comment, kept as part of the source
}
fn
names(attributes(fn))      # "srcref" (only)
names(attributes(body(fn))) # "srcref" "srcfile" "wholeSrcref"
f2 <- removeSource(fn)
f2
stopifnot(length(attributes(fn)) > 0,
           is.null(attributes(f2)),
           is.null(attributes(body(f2))))

## Source attribute of parse()d expressions,
## have {"srcref", "srcfile", "wholeSrcref"} :
E <- parse(text = "a <- x^y # power") ; names(attributes(E ))
E. <- removeSource(E)                  ; names(attributes(E.))
stopifnot(length(attributes(E )) > 0,
           is.null(attributes(E.)))
options(op) # reset to previous state
```

RHOME

R Home Directory

Description

Returns the location of the R home directory, which is the root of the installed R tree.

Usage

R RHOME

roman

Roman Numerals

Description

Simple manipulation of (a small set of) integer numbers as roman numerals.

Usage

```
as.roman(x)
.romans

r1 + r2
r1 <= r2
max(r1)
sum(r2)
```

Arguments

| | |
|--------|-------------------------------------------------------------|
| x | a numeric or character vector of arabic or roman numerals. |
| r1, r2 | a roman number vector, i.e., of <code>class</code> "roman". |

Details

`as.roman` creates objects of class "roman" which are internally represented as integers, and have suitable methods for printing, formatting, subsetting, coercion, etc, see `methods(class = "roman")`.

Arithmetic ("[Arith](#)"), Comparison ("[Compare](#)") and ("[Logic](#)"), i.e., all "[Ops](#)" group operations work as for regular numbers via R's integer functionality.

Only numbers between 1 and 3999 have a unique representation as roman numbers, and hence others result in `as.roman(NA)`.

`.romans` is the basic dictionary, a named `character` vector.

Examples

```
## First five roman 'numbers'.
(y <- as.roman(1 : 5))
## Middle one.
y[3]
## Current year as a roman number.
```

```

(y <- as.roman(format(Sys.Date(), "%Y")))
## Today, and 10, 20, 30, and 100 years ago ...
y - 10*c(0:3,10)

## mixture of arabic and roman numbers :
as.roman(c(NA, 1:3, "", strrep("I", 1:6))) # + NA with a warning for "IIIIII"
cc <- c(NA, 1:3, strrep("I", 0:5))
(rc <- as.roman(cc)) # two NAs: 0 is not "roman"
(ic <- as.integer(rc)) # works automatically [without an explicit method]
rNA <- as.roman(NA)
## simple consistency checks -- arithmetic when result is in {1,2,..,3999} :
stopifnot(identical(rc, as.roman(rc)), # as.roman(.) is "idempotent"
           identical(rc + rc + (3*rc), rc*5),
           identical(ic, c(NA, 1:3, NA, 1:5)),
           identical(as.integer(5*rc), 5L*ic),
           identical(as.numeric(rc), as.numeric(ic)),
           identical(rc[1], rNA),
           identical(as.roman(0), rNA),
           identical(as.roman(NA_character_), rNA),
           identical(as.list(rc), as.list(ic)))
## Non-Arithmetic 'Ops' :
stopifnot(exprs = {
  # Comparisons :
  identical(ic < 1:5, rc < 1:5)
  identical(ic < 1:5, rc < as.roman(1:5))
  # Logic [integers |>-> logical] :
  identical(rc & TRUE, ic & TRUE)
  identical(rc & FALSE, ic & FALSE)
  identical(rc | FALSE, ic | FALSE)
  identical(rc | NA, ic | NA)
})
## 'Summary' group functions (and comparison):
(rc. <- rc[!is.na(rc)])
stopifnot(exprs = {
  identical(min(rc), as.roman(NA))
  identical(min(rc, na.rm=TRUE),
            as.roman(min(ic, na.rm=TRUE)))
  identical(range(rc.),
            as.roman(range(as.integer(rc))))
  identical(sum(rc, na.rm=TRUE), as.roman("XXI"))
  identical(format(prod(rc, na.rm=TRUE)), "DCCXX")
  format(prod(rc.)) == "DCCXX"
})

```

Description

Enable or disable profiling of the execution of R expressions.

Usage

```
Rprof(filename = "Rprof.out", append = FALSE, interval = 0.02,
       memory.profiling = FALSE, gc.profiling = FALSE,
       line.profiling = FALSE, filter.callframes = FALSE,
       numfiles = 100L, bufsize = 10000L,
       event = c("default", "cpu", "elapsed"))
```

Arguments

| | |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| filename | The file to be used for recording the profiling results. Set to NULL or "" to disable profiling. |
| append | logical: should the file be over-written or appended to? |
| interval | real: distance (time interval) between samples in seconds. |
| memory.profiling | logical: write memory use information to the file? |
| gc.profiling | logical: record whether GC is running? |
| line.profiling | logical: write line locations to the file? |
| filter.callframes | logical: filter out intervening call frames of the call tree. See the filtering out call frames section. |
| numfiles, bufsize | integers: line profiling memory allocation |
| event | character: profiling event, character vector of length one, "elapsed" for elapsed (real, wall-clock) time and "cpu" for CPU time, both measured in seconds. "default" is the default event on the platform, one of the two. See the 'Details'. |

Details

Enabling profiling automatically disables any existing profiling to another or the same file.

Profiling works by writing out the call stack every interval seconds (units of the profiling event), to the file specified. Either the [summaryRprof](#) function or the wrapper script R CMD Rprof can be used to process the output file to produce a summary of the usage; use R CMD Rprof --help for usage information.

Exactly what is measured is subtle and depends on the profiling event.

With "elapsed" (the default and only supported event on Windows): it is time that the R process is running and executing an R command. It is not however just CPU time, for if readline() is waiting for input, that counts as well. It is also known as 'elapsed' time.

With "cpu" (the default on Unix and typically the preferred event for identifying performance bottlenecks), it is CPU time of the R process, so for example excludes time when R is waiting for input or for processes run by [system](#) to return. It may go slower than "elapsed" when the process is often waiting for I/O to finish, but it may go faster with actively computing concurrent threads (say via OpenMP) on a multi-core system.

Note that the (timing) interval cannot be too small. With "cpu", the time spent in each profiling step is currently added to the interval. With all profiling events, the computation in each profiling

step causes perturbation to the observed system and biases the results. What is feasible is machine-dependent. On Linux, R requires the interval to be at least 10ms, on all other platforms at least 1ms. Shorter intervals will be rounded up with a warning.

The "default" profiling event is "elapsed" on Windows and "cpu" on Unix.

Support for "elapsed" event on Unix is new and considered experimental. To reduce the risk of missing a sample, R tries to use the (real-time) FIFO scheduling policy with the maximum scheduling priority for an internal thread which initiates collection of each sample. If setting that priority fails, it tries to use the maximum scheduling priority of the current scheduling policy, falling back to the current scheduling parameters. On Linux, regular users are typically not allowed to use the real-time scheduling priorities. This can be usually allowed via PAM (e.g. `/etc/security/limits.conf`), see the OS documentation for details. The priorities only matter when profiling a system under high load.

Functions will only be recorded in the profile log if they put a context on the call stack (see [sys.calls](#)). Some [primitive](#) functions do not do so: specifically those which are of [type](#) "special" (see the 'R Internals' manual for more details).

Individual statements will be recorded in the profile log if `line.profiling` is TRUE, and if the code being executed was parsed with source references. See [parse](#) for a discussion of source references. By default the statement locations are not shown in [summaryRprof](#), but see that help page for options to enable the display.

Filtering Out Call Frames

Lazy evaluation makes the call stack more complex because intervening call frames are created between the time arguments are applied to a function, and the time they are effectively evaluated. When the call stack is represented as a tree, these intervening frames appear as sibling nodes. For instance, evaluating `try(EXPR)` produces the following call tree, at the time EXPR gets evaluated:

```
1. +-base::try(EXPR)
2. | \-base::tryCatch(...)
3. |   \-base::tryCatchList(expr, classes, parentenv, handlers)
4. |     \-base::tryCatchOne(expr, names, parentenv, handlers[[1L]])
5. |       \-base::doTryCatch(return(expr), name, parentenv, handler)
6. \-EXPR
```

Lines 2 to 5 are intervening call frames, the last of which finally triggered evaluation of EXPR. Setting `filter.callframes` to TRUE simplifies the profiler output by removing all sibling nodes of intervening frames.

The same kind of call frame filtering is applied with `eval()` frames. When you call `eval()`, two frames are pushed on the stack to ensure a continuity between frames. Say we have these definitions:

```
calling <- function() evaluator(quote(called()), environment())
evaluator <- function(expr, env) eval(expr, env)
called <- function() EXPR()
```

`calling()` calls `called()` in its own environment, via `eval()`. The latter is called indirectly through `evaluator()`. The net effect of this code is identical to just calling `called()` directly, without the intermediaries. However, the full call stack looks like this:

```

1. calling()
2. \-evaluator(quote(called()), environment())
3.   \-base::eval(expr, env)
4.     \-base::eval(expr, env)
5.       \-called()
6.         \-EXPR()

```

When call frame filtering is turned on, the true calling environment of `called()` is looked up, and the filtered call stack looks like this:

```

1. calling()
5. \-called()
6.   \-EXPR()

```

If the calling environment is not on the stack, the function called by `eval()` becomes a root node. Say we have:

```
calling <- function() evaluator(quote(called()), new.env())
```

With call frame filtering we then get the following filtered call stack:

```

5. called()
6. \-EXPR()

```

Note

On Unix-alikes: Profiling is not available on all platforms. By default, support for profiling is compiled in if possible – configure R with ‘`--disable-R-profiling`’ to change this.

As R CPU profiling uses the same mechanisms as C profiling, the two cannot be used together, so do not use `Rprof(event = "cpu")` (the default) in an executable built for C-level profiling (such as using the GCC option ‘`-p`’ or ‘`-pg`’).

On Windows: `filename` can be a UTF-8-encoded filepath that cannot be translated to the current locale.

The profiler interrupts R asynchronously, and it cannot allocate memory to store results as it runs. This affects line profiling, which needs to store an unknown number of file pathnames. The `numfiles` and `bufsize` arguments control the size of pre-allocated buffers to hold these results: the former counts the maximum number of paths, the latter counts the numbers of bytes in them. If the profiler runs out of space it will skip recording the line information for new files, and issue a warning when `Rprof(NULL)` is called to finish profiling.

See Also

The chapter on “Tidying and profiling R code” in ‘Writing R Extensions’: [RShowDoc\("R-exts"\)](#).

[summaryRprof](#) to analyse the output file.

[tracemem](#), [Rprofmem](#) for other ways to track memory use.

Examples

```
## Not run: Rprof()
## some code to be profiled
Rprof(NULL)
## some code NOT to be profiled
Rprof(append = TRUE)
## some code to be profiled
Rprof(NULL)
## ...
## Now post-process the output as described in Details

## End(Not run)
```

Rprofmem

*Enable Profiling of R's Memory Use***Description**

Enable or disable reporting of memory allocation in R.

Usage

```
Rprofmem(filename = "Rprofmem.out", append = FALSE, threshold = 0)
```

Arguments

| | |
|-----------|----------------------------------------------------------------------------------------------------|
| filename | The file to be used for recording the memory allocations. Set to NULL or "" to disable reporting. |
| append | logical: should the file be over-written or appended to? |
| threshold | numeric: allocations on R's "large vector" heap larger than this number of bytes will be reported. |

Details

Enabling profiling automatically disables any existing profiling to another or the same file.

Profiling writes the call stack to the specified file every time malloc is called to allocate a large vector object or to allocate a page of memory for small objects. The size of a page of memory and the size above which malloc is used for vectors are compile-time constants, by default 2000 and 128 bytes respectively.

The profiler tracks allocations, some of which will be to previously used memory and will not increase the total memory use of R.

Value

None

Note

The memory profiler slows down R even when not in use, and so is a compile-time option. (It is enabled in a standard Windows build of R.)

The memory profiler can be used at the same time as other R and C profilers.

See Also

The R sampling profiler, [Rprof](#) also collects memory information.

[tracemem](#) traces duplications of specific objects.

The chapter on ‘Tidying and profiling R code’ in the ‘Writing R Extensions’ manual.

Examples

```
## Not run:
## not supported unless R is compiled to support it.
Rprofmem("Rprofmem.out", threshold = 1000)
example(glm)
Rprofmem(NULL)
noquote(readLines("Rprofmem.out", n = 5))

## End(Not run)
```

Rscript

Scripting Front-End for R

Description

This is an alternative front end for use in ‘#!’ scripts and other scripting applications.

Usage

```
Rscript [options] file [args]
Rscript [options] -e expr [-e expr2 ...] [args]
```

Arguments

| | |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| options | a list of options, all beginning with ‘--’. These can be any of the options of the standard R front-end, and also those described in the details. |
| expr, expr2 | R expression(s), properly quoted. |
| file | the name of a file containing R commands. ‘-’ indicates ‘stdin’. |
| args | arguments to be passed to the script in file or expressions supplied via ‘-e’. |

Details

Rscript --help gives details of usage, and Rscript --version gives the version of Rscript.

Other invocations invoke the R front-end with selected options. This front-end is convenient for writing ‘#!’ scripts since it is an executable and takes file directly as an argument. Options ‘--no-echo --no-restore’ are always supplied: these imply ‘--no-save’. Arguments that contain spaces cannot be specified directly on the ‘#!’ line, because spaces and tabs are interpreted as delimiters and there is no way to protect them from this interpretation on the ‘#!’ line. (The standard Windows command line has no concept of ‘#!’ scripts, but Cygwin shells do.)

Either one or more ‘-e’ options or file should be supplied. When using ‘-e’ options be aware of the quoting rules in the shell used: see the examples.

The prescribed order of arguments is important: e.g. ‘--verbose’ specified after ‘-e’ will be part of args and passed to the expression; the same will happen to ‘-e’ specified after file.

Additional options accepted as part of options (before file or ‘-e’) are

‘--verbose’ gives details of what Rscript is doing.

‘--default-packages=list’ where list is a comma-separated list of package names or NULL.
Sets the environment variable R_DEFAULT_PACKAGES which determines the packages loaded on startup.

Spaces are allowed in expr and file (but will need to be protected from the shell in use, if any, for example by enclosing the argument in quotes).

If ‘--default-packages’ is not used, then Rscript checks the environment variable R_SCRIPT_DEFAULT_PACKAGES. If this is set, then it takes precedence over R_DEFAULT_PACKAGES.

Normally the version of R is determined at installation, but this can be overridden by setting the environment variable RHOME.

`stdin()` refers to the input file, and `file("stdin")` to the stdin file stream of the process.

Note

Rscript is only supported on systems with the `execv` system call.

Examples

```
## Not run:
Rscript -e 'date()' -e 'format(Sys.time(), "%a %b %d %X %Y")'

# Get the same initial packages in the same order as default R:
Rscript --default-packages=methods,datasets,utils,grDevices,graphics,stats -e 'sessionInfo()'

## example #! script for a Unix-alike
## (arguments given on the #! line end up as [options] to Rscript, while
## arguments passed to the #! script end up as [args], so available to
## commandArgs())
#! /path/to/Rscript --vanilla --default-packages=utils
args <- commandArgs(TRUE)
res <- try(install.packages(args))
if(inherits(res, "try-error")) q(status=1) else q()
```

```
## End(Not run)
```

RShowDoc*Show R Manuals and Other Documentation*

Description

Utility function to find and display R documentation.

Usage

```
RShowDoc(what, type = c("pdf", "html", "txt"), package)
```

Arguments

| | |
|---------|-------------------------------------------------------------------------------------------------------|
| what | a character string: see ‘Details’. |
| type | an optional character string giving the preferred format. Can be abbreviated. |
| package | an optional character string specifying the name of a package within which to look for documentation. |

Details

what can specify one of several different sources of documentation, including the R manuals (R-admin, R-data, R-exts, R-intro, R-ints, R-lang), NEWS, COPYING (the GPL licence), any of the licenses in ‘share/licenses’, FAQ (also available as R-FAQ), and the files in ‘[R_HOME](#)/doc’.

Only on Windows, the R for Windows FAQ is specified by rw-FAQ.

If package is supplied, documentation is looked for in the ‘doc’ and top-level directories of an installed package of that name.

If what is missing a brief usage message is printed.

The documentation types are tried in turn starting with the first specified in type (or “pdf” if none is specified).

Value

A invisible character string given the path to the file found.

See Also

For displaying regular help files, [help](#) (or [?](#)) and [help.start](#).

For type = “txt”, [file.show](#) is used. [vignettes](#) are nicely viewed via `RShowDoc(*, package= .)`.

Examples

```
RShowDoc("R-lang")
RShowDoc("FAQ", type = "html")
RShowDoc("frame", package = "grid")
RShowDoc("changes.txt", package = "grid")
RShowDoc("NEWS", package = "MASS")
```

RSiteSearch

Search for Key Words or Phrases in Documentation

Description

Search for key words or phrases in various documentation, such as R manuals, help pages of base and CRAN packages, vignettes, task views and others, using the search engine at <https://search.r-project.org> and view them in a web browser.

Usage

```
RSiteSearch(string,
             restrict = c("functions", "descriptions", "news", "Rfunctions",
                          "Rmanuals", "READMEs", "views", "vignettes"),
             format,
             sortby = c("score", "date:late", "date:early", "subject",
                        "subject:descending", "size", "size:descending"),
             matchesPerPage = 20,
             words = c("all", "any"))
```

Arguments

| | |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| string | A character string specifying word(s) or phrase(s) to search. If the words are to be searched as one entity, enclose them either in (escaped) quotes or in braces. |
| restrict | A character vector, typically of length greater than one. Values can be abbreviated. Possible areas to search in: functions for help pages of CRAN packages, descriptions for extended descriptions of CRAN packages, news for package NEWS, Rfunctions for help pages of R base packages, Rmanuals for R manuals, READMEs for 'README' files of CRAN packages, views for task views, vignettes for package vignettes. |
| format | deprecated. |
| sortby | character string (can be abbreviated) indicating how to sort the search results: (score, date:late for sorting by date with latest results first, date:early for earliest first, subject for captions in alphabetical order, subject:descending for reverse alphabetical order, size or size:descending for size.) |
| matchesPerPage | How many items to show per page. |
| words | Show results matching all words/phrases (default) or any of them. |

Details

This function is designed to work with the search site at <https://search.r-project.org>.

Unique partial matches will work for all arguments. Each new browser window will stay open unless you close it.

Value

(Invisibly) the complete URL passed to the browser, including the query string.

Author(s)

Andy Liaw and Jonathan Baron and Gennadiy Starostin

See Also

[help.search](#), [help.start](#) for local searches.

[browseURL](#) for how the help file is displayed.

Examples

```
# need Internet connection
## for phrase searching you may use (escaped) double quotes or brackets
RSiteSearch("{logistic regression} \"glm object\"")
RSiteSearch('"logistic regression"')

## Search in vignettes and help files of R base packages
## store the query string:
fullquery <- RSiteSearch("lattice", restrict = c("vignettes", "Rfunctions"))
fullquery # a string of 112 characters
```

rtags

An Etags-like Tagging Utility for R

Description

rtags provides etags-like indexing capabilities for R code, using R's own parser.

Usage

```
rtags(path = ".", pattern = "\\.[RrSs]$",
      recursive = FALSE,
      src = list.files(path = path, pattern = pattern,
                      full.names = TRUE,
                      recursive = recursive),
      keep.re = NULL,
      ofile = "", append = FALSE,
      verbose = getOption("verbose"),
      type = c("etags", "ctags"))
```

Arguments

| | |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| path, pattern, recursive | Arguments passed on to <code>list.files</code> to determine the files to be tagged. By default, these are all files with extension <code>‘.R’</code> , <code>‘.r’</code> , <code>‘.S’</code> , and <code>‘.s’</code> in the current directory. These arguments are ignored if <code>src</code> is specified. |
| src | A vector of file names to be indexed. |
| keep.re | A regular expression further restricting <code>src</code> (the files to be indexed). For example, specifying <code>keep.re = "/R/[^/]*\\.R\$"</code> will only retain files with extension <code>‘.R’</code> inside a directory named <code>‘R’</code> . |
| ofile | Passed on to <code>cat</code> as the file argument; typically the output file where the tags will be written (<code>"TAGS"</code> or <code>"tags"</code> by convention). By default, the output is written to the R console (unless redirected). |
| append | Logical, indicating whether the output should overwrite an existing file, or append to it. |
| verbose | Logical. If TRUE, file names are echoed to the R console as they are processed. |
| type | Character string specifying whether emacs style (<code>"etags"</code>) or vi style (<code>"ctags"</code>) tags are to be generated. |

Details

Many text editors allow definitions of functions and other language objects to be quickly and easily located in source files through a tagging utility. This functionality requires the relevant source files to be preprocessed, producing an index (or tag) file containing the names and their corresponding locations. There are multiple tag file formats, the most popular being the vi-style `ctags` format and the emacs-style `etags` format. Tag files in these formats are usually generated by the `ctags` and `etags` utilities respectively. Unfortunately, these programs do not recognize R code syntax. They do allow tagging of arbitrary language files through regular expressions, but this too is insufficient.

The `rtags` function is intended to be a tagging utility for R code. It parses R code files (using R's parser) and produces tags in both `etags` and `ctags` formats. The support for vi-style `ctags` is rudimentary, and was adapted from a patch by Neal Fultz; see [PR#17214](#).

It may be more convenient to use the command-line wrapper script `R CMD rtags`.

Rtangle

R Driver for Stangle

Description

A driver for [Stangle](#) that extracts R code chunks. Notably all `RtangleSetup()` arguments may be used as arguments in the [Stangle\(\)](#) call.

Usage

```
Rtangle()
RtangleSetup(file, syntax, output = NULL, annotate = TRUE,
             split = FALSE, quiet = FALSE, drop.evalFALSE = FALSE, ...)
```

Arguments

| | |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>file</code> | name of Sweave source file. See the description of the corresponding argument of Sweave . |
| <code>syntax</code> | an object of class <code>SweaveSyntax</code> . |
| <code>output</code> | name of output file used unless <code>split = TRUE</code> : see ‘Details’. |
| <code>annotate</code> | a logical or function . When true, as by default, code chunks are separated by comment lines specifying the names and line numbers of the code chunks. If FALSE the decorating comments are omitted. Alternatively, <code>annotate</code> may be a function, see section ‘Chunk annotation’. |
| <code>split</code> | split output into a file for each code chunk? |
| <code>quiet</code> | logical to suppress all progress messages. |
| <code>drop.evalFALSE</code> | logical; When false, as by default, all chunks with option <code>eval = FALSE</code> are <i>commented out</i> in the output; otherwise (<code>drop.evalFALSE = TRUE</code>) they are omitted entirely. |
| <code>...</code> | additional named arguments setting defaults for further options listed in ‘Supported Options’. |

Details

Unless `split = TRUE`, the default name of the output file is `basename(file)` with an extension corresponding to the Sweave syntax (e.g., ‘Rnw’, ‘Stex’) replaced by ‘R’. File names “stdout” and “stderr” are interpreted as the output and message connection respectively.

If splitting is selected (including by the options in the file), each chunk is written to a separate file with extension the name of the ‘engine’ (default ‘.R’).

Note that this driver does more than simply extract the code chunks verbatim, because chunks may re-use earlier chunks.

Chunk annotation (annotate)

By default `annotate = TRUE`, the annotation is of one of the forms

```
#####
### code chunk number 3: viewport
#####

#####
### code chunk number 18: grid.Rnw:647-648
#####

#####
### code chunk number 19: trellisdata (eval = FALSE)
#####
```

using either the chunk label (if present, i.e., when specified in the source) or the file name and line numbers.

`annotate` may be a function with formal arguments (`options`, `chunk`, `output`), e.g. to produce less dominant chunk annotations; see `Rtangle()$runcode` how it is called instead of the default.

Supported Options

Rtangle supports the following options for code chunks (the values in parentheses show the default values):

engine: character string (“R”). Only chunks with engine equal to “R” or “S” are processed.

keep.source: logical (TRUE). If `keep.source == TRUE` the original source is copied to the file. Otherwise, deparsed source is output.

eval: logical (TRUE). If FALSE, the code chunk is copied across but commented out.

prefix Used if `split = TRUE`. See `prefix.string`.

prefix.string: a character string, default is the name of the source file (without extension). Used if `split = TRUE` as the prefix for the filename if the chunk has no label, or if it has a label and `prefix = TRUE`. Note that this is used as part of filenames, so needs to be portable.

show.line.nos logical (FALSE). Should the output be annotated with comments showing the line number of the first code line of the chunk?

Examples

```
nmRnw <- "example-1.Rnw"
exfile <- system.file("Sweave", nmRnw, package = "utils")
## Create R source file
Stangle(exfile)
nmR <- sub("Rnw$", "R", nmRnw) # the (default) R output file name
if(interactive()) file.show("example-1.R")

## Smaller R source file with custom annotation:
my.Ann <- function(options, chunk, output) {
  cat("### chunk #", options$chunknr, ": ",
      if(!is.null(ol <- options$label)) ol else .RtangleCodeLabel(chunk),
      if(!options$eval) " (eval = FALSE)", "\n",
      file = output, sep = "")
}
Stangle(exfile, annotate = my.Ann)
if(interactive()) file.show("example-1.R")

Stangle(exfile, annotate = my.Ann, drop.evalFALSE=TRUE)
if(interactive()) file.show("example-1.R")
```

RweaveLatex

R/LaTeX Driver for Sweave

Description

A driver for [Sweave](#) that translates R code chunks in \LaTeX files by “running them”, i.e., [parse\(\)](#) and [eval\(\)](#) each.

Usage

```
RweaveLatex()
```

```
RweaveLatexSetup(file, syntax, output = NULL, quiet = FALSE,
                  debug = FALSE, stylepath, ...)
```

Arguments

| | |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| file | Name of Sweave source file. See the description of the corresponding argument of Sweave . |
| syntax | An object of class SweaveSyntax. |
| output | Name of output file. The default is to remove extension ‘.nw’, ‘.Rnw’ or ‘.Snw’ and to add extension ‘.tex’. Any directory paths in file are also removed such that the output is created in the current working directory. |
| quiet | If TRUE all progress messages are suppressed. |
| debug | If TRUE, input and output of all code chunks is copied to the console. |
| stylepath | See ‘Details’. |
| ... | named values for the options listed in ‘Supported Options’. |

Details

The \LaTeX file generated needs to contain the line ‘`\usepackage{Sweave}`’, and if this is not present in the Sweave source file (possibly in a comment), it is inserted by the RweaveLatex driver as last line before the ‘`\begin{document}`’ statement. If `stylepath = TRUE`, a hard-coded path to the file ‘Sweave.sty’ in the R installation is set in place of Sweave. The hard-coded path makes the \LaTeX file less portable, but avoids the problem of installing the current version of ‘Sweave.sty’ to some place in your TeX input path. However, TeX may not be able to process the hard-coded path if it contains spaces (as it often will under Windows) or TeX special characters.

The default for `stylepath` is now taken from the environment variable `SWEAVE_STYLEPATH_DEFAULT`, or is FALSE if that is unset or empty. If set, it should be exactly TRUE or FALSE: any other values are taken as FALSE.

The simplest way for frequent Sweave users to ensure that ‘Sweave.sty’ is in the TeX input path is to add ‘`R_HOME/share/texmf`’ as a ‘texmf tree’ (‘root directory’ in the parlance of the ‘MiKTeX settings’ utility).

By default, ‘Sweave.sty’ loads the ‘graphicx’ \LaTeX package and sets the width of all included graphics to:
‘`\setkeys{Gin}{width=0.8\textwidth}`’.

This setting (defined in the ‘graphicx’ package) affects the width size option passed to the ‘`\includegraphics{}`’ directive for each plot file and in turn impacts the scaling of your plot files as they will appear in your final document.

Thus, for example, you may set `width=3` in your figure chunk and the generated graphics files will be set to 3 inches in width. However, the width of your graphic in your final document will be set to ‘`0.8\textwidth`’ and the height dimension will be scaled accordingly. Fonts and symbols will be similarly scaled in the final document.

You can adjust the default value by including the ‘`\setkeys{Gin}{width=...}`’ directive in your ‘.Rnw’ file after the ‘`\begin{document}`’ directive and changing the width option value as you prefer, using standard \LaTeX measurement values.

If you wish to override this default behavior entirely, you can add a ‘`\usepackage[nogin]{Sweave}`’ directive in your preamble. In this case, no size/scaling options will be passed to the ‘`\includegraphics{}`’ directive and the height and width options

will determine both the runtime generated graphic file sizes and the size of the graphics in your final document.

'Sweave.sty' also supports the '[nofontenc]' option, which skips the default inclusion of '\usepackage[T1]{fontenc}' for pdfTeX processing.

It also supports the '[inconsolata]' option, to render monospaced text in inconsolata, the font used by default for R help pages.

The use of fancy quotes (see [sQuote](#)) can cause problems when setting R output in non-UTF-8 locales (note that pdfTeX assumes UTF-8 by default since 2018). Either set [options](#)(useFancyQuotes = FALSE) or arrange that L^AT_EX is aware of the encoding used and ensure that typewriter fonts containing directional quotes are used.

Some L^AT_EX graphics drivers do not include '.png' or '.jpg' in the list of known extensions. To enable them, add something like '\DeclareGraphicsExtensions{.png,.pdf,.jpg}' to the preamble of your document or check the behavior of your graphics driver. When both pdf and png are TRUE both files will be produced by Sweave, and their order in the 'DeclareGraphicsExtensions' list determines which will be used by pdf_latex.

Supported Options

RweaveLatex supports the following options for code chunks (the values in parentheses show the default values). Character string values should be quoted when passed from [Sweave](#) through ... but not when used in the header of a code chunk.

engine: character string ("R"). Only chunks with engine equal to "R" or "S" are processed.

echo: logical (TRUE). Include R code in the output file?

keep.source: logical (TRUE). When echoing, if TRUE the original source is copied to the file. Otherwise, deparsed source is echoed.

eval: logical (TRUE). If FALSE, the code chunk is not evaluated, and hence no text nor graphical output produced.

results: character string ("verbatim"). If "verbatim", the output of R commands is included in the verbatim-like 'Soutput' environment. If "tex", the output is taken to be already proper L^AT_EX markup and included as is. If "hide" then all output is completely suppressed (but the code executed during the weave). Values can be abbreviated.

print: logical (FALSE). If TRUE, this forces auto-printing of all expressions.

term: logical (TRUE). If TRUE, visibility of values emulates an interactive R session: values of assignments are not printed, values of single objects are printed. If FALSE, output comes only from explicit [print](#) or similar statements.

split: logical (FALSE). If TRUE, text output is written to separate files for each code chunk.

strip.white: character string ("true"). If "true", blank lines at the beginning and end of output are removed. If "all", then all blank lines are removed from the output. If "false" then blank lines are retained.

A 'blank line' is one that is empty or includes only whitespace (spaces and tabs).

Note that blank lines in a code chunk will usually produce a prompt string rather than a blank line on output.

prefix: logical (TRUE). If TRUE generated filenames of figures and output all have the common prefix given by the `prefix.string` option: otherwise only unlabelled chunks use the prefix.

prefix.string: a character string, default is the name of the source file (without extension). Note that this is used as part of filenames, so needs to be portable.

include: logical (TRUE), indicating whether input statements for text output (if `split = TRUE`) and `\includegraphics` statements for figures should be auto-generated. Use `include = FALSE` if the output should appear in a different place than the code chunk (by placing the input line manually).

fig: logical (FALSE), indicating whether the code chunk produces graphical output. Note that only one figure per code chunk can be processed this way. The labels for figure chunks are used as part of the file names, so should preferably be alphanumeric.

eps: logical (FALSE), indicating whether EPS figures should be generated. Ignored if `fig = FALSE`.

pdf: logical (TRUE), indicating whether PDF figures should be generated. Ignored if `fig = FALSE`.

pdf.version, pdf.encoding, pdf.compress: passed to `pdf` to set the version, encoding and compression (or not). Defaults taken from `pdf.options()`.

png: logical (FALSE), indicating whether PNG figures should be generated. Ignored if `fig = FALSE`. Only available in $R \geq 2.13.0$.

jpeg: logical (FALSE), indicating whether JPEG figures should be generated. Ignored if `fig = FALSE`. Only available in $R \geq 2.13.0$.

grdevice: character (NULL): see section ‘Custom Graphics Devices’. Ignored if `fig = FALSE`. Only available in $R \geq 2.13.0$.

width: numeric (6), width of figures in inches. See ‘Details’.

height: numeric (6), height of figures in inches. See ‘Details’.

resolution: numeric (300), resolution in pixels per inch: used for PNG and JPEG graphics. Note that the default is a fairly high value, appropriate for high-quality plots. Something like 100 is a better choice for package vignettes.

concordance: logical (FALSE). Write a concordance file to link the input line numbers to the output line numbers.

figs.only: logical (FALSE). By default each figure chunk is run once, then re-run for each selected type of graphics. That will open a default graphics device for the first figure chunk and use that device for the first evaluation of all subsequent chunks. If this option is true, the figure chunk is run only for each selected type of graphics, for which a new graphics device is opened and then closed.

In addition, users can specify further options, either in the header of an individual code section or in a `\SweaveOpts{}` line in the document. For unknown options, their type is set at first use.

Custom Graphics Devices

If option `grdevice` is supplied for a code chunk with both `fig` and `eval` true, the following call is made

```
get(options$grdevice, envir = .GlobalEnv)(name=, width=,
                                           height=, options)
```

which should open a graphics device. The chunk’s code is then evaluated and `dev.off` is called. Normally a function of the name given will have been defined earlier in the Sweave document, e.g.

```
<<results=hide>>=
my.Swd <- function(name, width, height, ...)
  grDevices::png(filename = paste(name, "png", sep = "."),
    width = width, height = height, res = 100,
    units = "in", type = "quartz", bg = "transparent")
@
```

Alternatively for R >= 3.4.0, if the function exists in a package (rather than the `.GlobalEnv`) it can be used by setting `grdevice = "pkg:my.Swd"` (or with `'::'` instead of `':'` if the function is not exported).

Currently only one custom device can be used for each chunk, but different devices can be used for different chunks.

A replacement for [dev.off](#) can be provided as a function with suffix `.off`, e.g. `my.Swd.off()` or `pkg:my.Swd.off()`, respectively.

Hook Functions

Before each code chunk is evaluated, zero or more hook functions can be executed. If `getOption("SweaveHooks")` is set, it is taken to be a named list of hook functions. For each *logical* option of a code chunk (`echo`, `print`, ...) a hook can be specified, which is executed if and only if the respective option is `TRUE`. Hooks must be named elements of the list returned by `getOption("SweaveHooks")` and be functions taking no arguments. E.g., if option `"SweaveHooks"` is defined as `list(fig = foo)`, and `foo` is a function, then it would be executed before the code in each figure chunk. This is especially useful to set defaults for the graphical parameters in a series of figure chunks.

Note that the user is free to define new Sweave logical options and associate arbitrary hooks with them. E.g., one could define a hook function for a new option called `clean` that removes all objects in the workspace. Then all code chunks specified with `clean = TRUE` would start operating on an empty workspace.

[‘Sweave User Manual’](#), a vignette in the `utils` package.

[Sweave](#), [Rtangle](#)

Description

The file 'Rconsole' configures the R GUI (Rgui) console under MS Windows and `loadRconsole(*)` loads a new configuration.

The file 'Rdevga' configures the graphics devices `windows`, `win.graph`, `win.metafile` and `win.print`, as well as the bitmap devices `bmp`, `jpeg`, `png` and `tiff` (which use for type = "windows" use windows internally).

Usage

```
loadRconsole(file)
```

Arguments

| | |
|------|----------------------------------------------------------------------------------------------------------------|
| file | The file from which to load a new 'Rconsole' configuration. By default a file dialog is used to select a file. |
|------|----------------------------------------------------------------------------------------------------------------|

Details

There are system copies of these files in '`R_HOME\etc`'. Users can have personal copies of the files: these are looked for in the location given by the environment variable `R_USER`. The system files are read only if a corresponding personal file is not found.

If the environment variable `R_USER` is not set, the R system sets it to `HOME` if that is set (stripping any trailing slash), otherwise to the Windows 'personal' directory, otherwise to `{HOMEDRIVE}{HOMEPATH}` if `HOMEDRIVE` and `HOMEDRIVE` are both set otherwise to the working directory. This is as described in the file 'rw-FAQ'.

Value

Each of the files contains details in its comments of how to set the values.

At the time of writing 'Rdevga' configured the mapping of font numbers to fonts, and 'Rconsole' configured the appearance (single or multiple document interface, toolbar, status bar on MDI), size, font and colours of the GUI console, and whether resizing the console sets `options("width")`.

The file 'Rconsole' also configures the internal pager. This shares the font and colours of the console, but can be sized separately.

'Rconsole' can also set the initial positions of the console and the graphics device, as well as the size and position of the MDI workspace in MDI mode.

`loadRconsole` is called for its side effect of loading new defaults. It returns no useful value.

Chinese/Japanese/Korean

Users of these languages will need to select a suitable font for the console (perhaps MS Mincho) and for the graphics device (although the default Arial has many East Asian characters). It is essential that the font selected for the console has double-width East Asian characters – many monospaced fonts do not.

Note

The GUI preferences item on the Edit menu brings up an dialog box which can be used to edit the console settings, and to save them to a file.

This is only available on Windows.

[windows](#)

Examples

```
if(.Platform$OS.type == "windows") withAutoprint({
  ruser <- Sys.getenv("R_USER")
  cat("\n\nLocation for personal configuration files is\n  R_USER = ",
      ruser, "\n\n", sep = "")
  ## see if there are personal configuration files
  file.exists(file.path(ruser, c("Rconsole", "Rdevga"))))

## show the configuration files used
showConfig <- function(file)
{
  ruser <- Sys.getenv("R_USER")
  path <- file.path(ruser, file)
  if(!file.exists(path)) path <- file.path(R.home(), "etc", file)
  file.show(path, header = path)
}
showConfig("Rconsole")
})
```

savehistory

Load or Save or Display the Commands History

Description

Load or save or display the commands history.

Usage

```
loadhistory(file = ".Rhistory")
savehistory(file = ".Rhistory")

history(max.show = 25, reverse = FALSE, pattern, ...)

timestamp(stamp = date(),
  prefix = "##----- ", suffix = " -----##",
  quiet = FALSE)
```

Arguments

| | |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <code>file</code> | The name of the file in which to save the history, or from which to load it. The path is relative to the current working directory. |
| <code>max.show</code> | The maximum number of lines to show. <code>Inf</code> will give all of the currently available history. |
| <code>reverse</code> | logical. If true, the lines are shown in reverse order. Note: this is not useful when there are continuation lines. |
| <code>pattern</code> | A character string to be matched against the lines of the history. When supplied, only <i>unique</i> matching lines are shown. |
| <code>...</code> | Arguments to be passed to <code>grep</code> when doing the matching. |
| <code>stamp</code> | A value or vector of values to be written into the history. |
| <code>prefix</code> | A prefix to apply to each line. |
| <code>suffix</code> | A suffix to apply to each line. |
| <code>quiet</code> | If TRUE, suppress printing timestamp to the console. |

Details

There are several history mechanisms available for the different R consoles, which work in similar but not identical ways. Notably, there are different implementations for Unix and Windows.

Windows: The functions described here work in Rgui and interactive Rterm but not in batch use of Rterm nor in embedded/DCOM versions.

Unix-alikes: The functions described here work under the readline command-line interface but may not otherwise (for example, in batch use or in an embedded application). Note that R can be built without readline.

R.app, the console on macOS, has a separate and largely incompatible history mechanism, which by default uses a file `‘.Rapp.history’` and saves up to 250 entries. These functions are not currently implemented there.

The (readline on Unix-alikes) history mechanism is controlled by two environment variables: `R_HISTSIZE` controls the number of lines that are saved (default 512), and `R_HISTFILE` (default `‘.Rhistory’`) sets the filename used for the loading/saving of history if requested at the beginning/end of a session (but not the default for `loadhistory/savehistory`). There is no limit on the number of lines of history retained during a session, so setting `R_HISTSIZE` to a large value has no penalty unless a large file is actually generated.

These environment variables are read at the time of saving, so can be altered within a session by the use of `Sys.setenv`.

On Unix-alikes: Note that readline history library saves files with permission `0600`, that is with read/write permission for the user and not even read permission for any other account.

The `timestamp` function writes a timestamp (or other message) into the history and echos it to the console. On platforms that do not support a history mechanism only the console message is printed.

Note

If you want to save the history at the end of (almost) every interactive session (even those in which you do not save the workspace), you can put a call to `savehistory()` in `.Last`. See the examples.

Examples

```
## Not run:
## Save the history in the home directory: note that it is not
## (by default) read from there but from the current directory
.Last <- function()
  if(interactive()) try(savehistory("~/Rhistory"))

## End(Not run)
```

select.list

Select Items from a List

Description

Select item(s) from a character vector.

Usage

```
select.list(choices, preselect = NULL, multiple = FALSE,
            title = NULL, graphics = getOption("menu.graphics"))
```

Arguments

| | |
|-----------|-----------------------------------------------------------------------------------------------------------------------|
| choices | a character vector of items. |
| preselect | a character vector, or NULL. If non-null and if the string(s) appear in the list, the item(s) are selected initially. |
| multiple | logical: can more than one item be selected? |
| title | optional character string for window title, or NULL for no title. |
| graphics | logical: should a graphical widget be used? |

Details

The normal default is graphics = TRUE.

On Windows, this brings up a modal dialog box with a (scrollable) list of items, which can be selected by the mouse. If multiple is true, further items can be selected or deselected by holding the control key down whilst selecting, and shift-clicking can be used to select ranges. Normal termination is via the ‘OK’ button or by hitting Enter or double-clicking an item. Selection can be aborted via the ‘Cancel’ button or pressing Escape.

Under the macOS GUI, this brings up a modal dialog box with a (scrollable) list of items, which can be selected by the mouse.

On other Unix-like platforms it will use a Tcl/Tk listbox widget if possible.

If graphics is FALSE or no graphical widget is available it displays a text list from which the user can choose by number(s). The multiple = FALSE case uses [menu](#). Preselection is only supported for multiple = TRUE, where it is indicated by a "+" preceding the item.

It is an error to use select.list in a non-interactive session.

Value

A character vector of selected items. If `multiple` is `false` and no item was selected (or `Cancel` was used), `""` is returned. If `multiple` is `true` and no item was selected (or `Cancel` was used) then a character vector of length 0 is returned.

See Also

[menu](#), [tk_select.list](#) for a graphical version using Tcl/Tk.

Examples

```
## Not run:
select.list(sort(.packages(all.available = TRUE)))

## End(Not run)
```

sessionInfo

Collect Information About the Current R Session

Description

Get and report version information about R, the OS and attached or loaded packages.

The [print\(\)](#) and [toLatex\(\)](#) methods (for a "sessionInfo" object) show the locale and timezone information by default, when `locale` or `tzone` are `true`. The `system.codepage` is only shown when it is not empty, i.e., only on Windows, *and* if it differs from `code.page`, see below or [l10n_info\(\)](#).

Usage

```
sessionInfo(package = NULL)
## S3 method for class 'sessionInfo'
print(x, locale = TRUE, tzone = locale,
      RNG = !identical(x$RNGkind, .RNGdefaults), ...)
## S3 method for class 'sessionInfo'
toLatex(object, locale = TRUE, tzone = locale,
        RNG = !identical(object$RNGkind, .RNGdefaults), ...)
osVersion
```

Arguments

| | |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>package</code> | a character vector naming installed packages, or <code>NULL</code> (the default) meaning all attached packages. |
| <code>x</code> | an object of class "sessionInfo". |
| <code>object</code> | an object of class "sessionInfo". |
| <code>locale</code> | show locale, by default <code>tzone</code> , and (on Windows) code page information? |
| <code>tzone</code> | show time zone information? |
| <code>RNG</code> | show information on RNGkind() ? Defaults to <code>true</code> iff it differs from the R version's default, i.e., RNGversion(*) . |
| <code>...</code> | currently not used. |

Value

`sessionInfo()` returns an object of class "sessionInfo" which has `print` and `toLatex` methods. This is a list with components

| | |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>R.version</code> | a list, the result of calling <code>R.Version()</code> . |
| <code>platform</code> | a character string describing the platform R was built under. Where sub-architectures are in use this is of the form 'platform/sub-arch': 32-bit builds have (32-bit) appended |
| <code>running</code> | a character string (or possibly NULL), the same as <code>osVersion</code> , see below. |
| <code>RNGkind</code> | a character vector, the result of calling <code>RNGkind()</code> . |
| <code>matprod</code> | a character string, the result of calling <code>getOption("matprod")</code> . |
| <code>BLAS</code> | a character string, the result of calling <code>extSoftVersion()["BLAS"]</code> . |
| <code>LAPACK</code> | a character string, the result of calling <code>La_library()</code> . |
| <code>LA_version</code> | a character string, the result of calling <code>La_version()</code> . |
| <code>locale</code> | a character string, the result of calling <code>Sys.getlocale()</code> . |
| <code>tzzone</code> | a character string, the result of calling <code>Sys.timezone()</code> . |
| <code>tzcode_type</code> | a character string indicating source (system/internal) of the date-time conversion and printing functions. |
| <code>basePkgs</code> | a character vector of base packages which are attached. |
| <code>otherPkgs</code> | (not always present): a named list of the results of calling <code>packageDescription</code> on other attached packages. |
| <code>loadedOnly</code> | (not always present): a named list of the results of calling <code>packageDescription</code> on packages whose namespaces are loaded but are not attached. |

osVersion

`osVersion` is a character string (or possibly NULL on bizarre platforms) describing the OS and version which it is running under (as distinct from built under). This attempts to name a Linux distribution and give the OS name on an Apple Mac.

It is the same as `sessionInfo()$running` and created when loading the **utils** package.

Windows may report unexpected versions: see the help for `win.version`.

How OSes identify themselves and their versions can be arcane: where possible `osVersion` (and hence `sessionInfo()$running`) uses a human-readable form.

Where R was compiled under macOS 10.x (as the CRAN Intel distributions were prior to R 4.3.0) but running under 'Big Sur' or later, macOS reports itself as '10.16' (which R recognizes as 'Big Sur ...') and not '11', '12',

Note

The information on 'loaded' packages and namespaces is the *current* version installed at the location the package was loaded from: it can be wrong if another process has been changing packages during the session.

See Also

[R.version](#), [R_compiled_by](#)

Examples

```
sI <- sessionInfo()
sI
# The same, showing the RNGkind, but not the locale :
print(sI, RNG = TRUE, locale = FALSE)
toLatex(sI, locale = FALSE) # shortest; possibly desirable at end of report
```

| | |
|-----------------|------------------------------------|
| setRepositories | <i>Select Package Repositories</i> |
|-----------------|------------------------------------|

Description

Interact with the user to choose the package repositories to be used.

Usage

```
setRepositories(graphics = getOption("menu.graphics"),
               ind = NULL, addURLs = character(), name = NULL)
```

Arguments

| | |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| graphics | Logical. If true, use a graphical list: on Windows or macOS GUI use a list box, and on a Unix-alike if tcltk and an X server are available, use Tk widget. Otherwise use a text menu . |
| ind | NULL or a vector of integer indices, which have the same effect as if they were entered at the prompt for graphics = FALSE. |
| name | NULL or character vector of names of the repositories in the repository table which has the same effect as passing the corresponding indices to ind. |
| addURLs | A character vector of additional URLs: it is often helpful to use a named vector. |

Details

The default list of known repositories is stored in the file '[R_HOME](#)/etc/repositories'. That file can be edited for a site, or a user can have a personal copy in the file pointed to by the environment variable R_REPOSITORIES, or if this is unset, NULL or does not exist, in '[HOME](#)/.R/repositories', which will take precedence.

A Bioconductor mirror can be selected by setting [options](#)("BioC_mirror"), e.g. via [chooseBioCmirror](#) — the default value is "https://bioconductor.org". This version of R chooses Bioconductor version 3.19 by default, but that can be changed via the environment variable R_BIOC_VERSION.

The items that are preselected are those that are currently in [options](#)("repos") plus those marked as default in the list of known repositories.

The list of repositories offered depends on the setting of option "pkgType" as some repositories only offer a subset of types (e.g., only source packages or not macOS binary packages). Further, for binary packages some repositories (notably R-Forge) only offer packages for the current or recent versions of R. (Type "both" is equivalent to "source".)

Repository 'CRAN' is treated specially: the value is taken from the current setting of `getOption("repos")` if this has an element "CRAN": this ensures mirror selection is sticky.

This function requires the R session to be interactive unless `ind` or `name` is supplied. The latter overrides the former if both are supplied and values are not case-sensitive. If any of the supplied names does not match, an error is raised.

Value

This function is invoked mainly for its side effect of updating `options("repos")`. It returns (invisibly) the previous repos options setting (as a [list](#) with component `repos`) or `NULL` if no changes were applied.

Note

This does **not** set the list of repositories at startup: to do so set `options(repos =)` in a start up file (see help topic [Startup](#)) or via a customized 'repositories' file.

See Also

[chooseCRANmirror](#), [chooseBioCmirror](#), [install.packages](#).

Examples

```
## Not run:
setRepositories(addURLs =
  c(CRANxtras = "https://www.stats.ox.ac.uk/pub/RWin"))

## End(Not run)
oldrepos <- setRepositories(name = c("CRAN", "R-Forge"))
getOption("repos")
options(oldrepos) # restore
```

setWindowTitle

Set the Window Title or the Status Bar of the RGui in Windows

Description

Set or get the title of the R (i.e. RGui) window which will appear in the task bar, or set the status bar (if in use).

Usage

```
setWindowTitle(suffix, title = paste(getIdentification(), suffix))

getTitle()

getIdentification()

setStatusbar(text)
```

Arguments

| | |
|--------|--------------------------------------------------------------------------------|
| suffix | a character string to form part of the title |
| title | a character string forming the complete new title |
| text | a character string of up to 255 characters, to be displayed in the status bar. |

Details

setWindowTitle appends suffix to the normal window identification (RGui, R Console or Rterm). Use suffix = "" to reset the title.

getTitle gets the current title.

This sets the title of the frame in MDI mode, the title of the console for RGui --sdi, and the title of the window from which it was launched for Rterm. It has no effect in embedded uses of R.

getIdentification returns the normal window identification.

setStatusbar sets the text in the status bar of an MDI frame: if this is not currently shown it is selected and shown.

Value

The first three functions return a length 1 character vector.

setWindowTitle returns the previous window title (invisibly).

getTitle and getIdentification return the current window title and the normal window identification, respectively.

Note

These functions are only available on Windows and only make sense when using the Rgui. E.g., in Rterm (and hence in ESS) the title is not visible (but can be set and gotten), and in a version of RStudio it has been "", invariably.

Examples

```
if(.Platform$OS.type == "windows") withAutoprint({
## show the current working directory in the title, saving the old one
oldtitle <- setWindowTitle(getwd())
Sys.sleep(0.5)
## reset the title
setWindowTitle("")
})
```

```

Sys.sleep(0.5)
## restore the original title
setWindowTitle(title = oldtitle)
})

```

SHLIB

*Build Shared Object/DLL for Dynamic Loading***Description**

Compile the given source files and then link all specified object files into a shared object aka DLL which can be loaded into R using `dyn.load` or `library.dynam`.

Usage

R CMD SHLIB [options] [-o dllname] files

Arguments

| | |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| files | a list specifying the object files to be included in the shared object/DLL. You can also include the name of source files (for which the object files are automatically made from their sources) and library linking commands. |
| dllname | the full name of the shared object/DLL to be built, including the extension (typically <code>.so</code> on Unix systems, and <code>.dll</code> on Windows). If not given, the base-name of the object/DLL is taken from the basename of the first file. |
| options | Further options to control the processing. Use R CMD SHLIB <code>--help</code> for a current list. |

Details

R CMD SHLIB is the mechanism used by [INSTALL](#) to compile source code in packages. It will generate suitable compilation commands for C, C++, Objective C(++) and Fortran sources: Fortran 90/95 sources can also be used but it may not be possible to mix these with other languages (on most platforms it is possible to mix with C, but mixing with C++ rarely works).

Please consult section ‘Creating shared objects’ in the manual ‘Writing R Extensions’ for how to customize it (for example to add cpp flags and to add libraries to the link step) and for details of some of its quirks.

Items in files with extensions `.c`, `.cpp`, `.cc`, `.C`, `.f`, `.f90`, `.f95`, `.m` (Objective-C), `.M` and `.mm` (Objective-C++) are regarded as source files, and those with extension `.o` as object files. All other items are passed to the linker.

Objective C(++) support is optional when R was configured: their main usage is on macOS.

Note that the appropriate run-time libraries will be used when linking if C++, Fortran or Objective C(++) sources are supplied, but not for compiled object files from these languages.

Option `-n` (also known as `--dry-run`) will show the commands that would be run without actually executing them.

Note

Some binary distributions of R have SHLIB in a separate bundle, e.g., an R-devel RPM.

See Also

[COMPILE](#), [dyn.load](#), [library.dynam](#).

The ‘R Installation and Administration’ and ‘Writing R Extensions’ manuals, including the section on ‘Customizing package compilation’ in the former.

Examples

```
## Not run:
# To link against a library not on the system library paths:
R CMD SHLIB -o mylib.so a.f b.f -L/opt/acml3.5.0/gnu64/lib -lacml

## End(Not run)
```

shortPathName

Express File Paths in Short Form on Windows

Description

Convert file paths to the short form. This is an interface to the Windows API call GetShortPathNameW.

Usage

```
shortPathName(path)
```

Arguments

path character vector of file paths.

Details

For most file systems, the short form is the ‘DOS’ form with 8+3 path components and no spaces, and this used to be guaranteed. But some file systems on recent versions of Windows do not have short path names when the long-name path will be returned instead.

Value

A character vector. The path separator will be ‘\’. If a file path does not exist, the supplied path will be returned with slashes replaced by backslashes.

Note

This is only available on Windows.

See Also

[normalizePath](#).

Examples

```
if(.Platform$OS.type == "windows") withAutoprint({  
  cat(shortPathName(c(R.home(), tempdir())), sep = "\n")  
})
```

| | |
|-------------|-----------------------------------|
| sourceutils | <i>Source Reference Utilities</i> |
|-------------|-----------------------------------|

Description

These functions extract information from source references.

Usage

```
getSrcFilename(x, full.names = FALSE, unique = TRUE)  
getSrcDirectory(x, unique = TRUE)  
getSrcref(x)  
getSrcLocation(x, which = c("line", "column", "byte", "parse"),  
               first = TRUE)
```

Arguments

| | |
|------------|------------------------------------------------------------------|
| x | An object (typically a function) containing source references. |
| full.names | Whether to include the full path in the filename result. |
| unique | Whether to list only unique filenames/directories. |
| which | Which part of a source reference to extract. Can be abbreviated. |
| first | Whether to show the first (or last) location of the object. |

Details

Each statement of a function will have its own source reference if the "keep.source" option is TRUE. These functions retrieve all of them.

The components are as follows:

- line** The line number where the object starts or ends.
- column** The column number where the object starts or ends. Horizontal tabs are converted to spaces.
- byte** As for "column", but counting bytes, which may differ in case of multibyte characters (and horizontal tabs).
- parse** As for "line", but this ignores #line directives.

Value

getSrcFilename and getSrcDirectory return character vectors holding the filename/directory.

getSrcCref returns a list of "srcCref" objects or NULL if there are none.

getSrcLocation returns an integer vector of the requested type of locations.

See Also

[srcCref](#), [getParseData](#)

Examples

```
fn <- function(x) {  
  x + 1 # A comment, kept as part of the source  
}  
  
# Show the temporary file directory  
# where the example was saved  
  
getSrcDirectory(fn)  
getSrcLocation(fn, "line")
```

stack

Stack or Unstack Vectors from a Data Frame or List

Description

Stacking vectors concatenates multiple vectors into a single vector along with a factor indicating where each observation originated. Unstacking reverses this operation.

Usage

```
stack(x, ...)  
## Default S3 method:  
stack(x, drop=FALSE, ...)  
## S3 method for class 'data.frame'  
stack(x, select, drop=FALSE, ...)  
  
unstack(x, ...)  
## Default S3 method:  
unstack(x, form, ...)  
## S3 method for class 'data.frame'  
unstack(x, form, ...)
```

Arguments

| | |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x | a list or data frame to be stacked or unstacked. |
| select | an expression, indicating which variable(s) to select from a data frame. |
| form | a two-sided formula whose left side evaluates to the vector to be unstacked and whose right side evaluates to the indicator of the groups to create. Defaults to formula(x) in the data frame method for unstack. |
| drop | Whether to drop the unused levels from the “ind” column of the return value. |
| ... | further arguments passed to or from other methods. |

Details

The `stack` function is used to transform data available as separate columns in a data frame or list into a single column that can be used in an analysis of variance model or other linear model. The `unstack` function reverses this operation.

Note that `stack` applies to *vectors* (as determined by [is.vector](#)): non-vector columns (e.g., factors) will be ignored with a warning. Where vectors of different types are selected they are concatenated by [unlist](#) whose help page explains how the type of the result is chosen.

These functions are generic: the supplied methods handle data frames and objects coercible to lists by [as.list](#).

Value

`unstack` produces a list of columns according to the formula form. If all the columns have the same length, the resulting list is coerced to a data frame.

`stack` produces a data frame with two columns:

| | |
|--------|------------------------------------------------------------------------|
| values | the result of concatenating the selected vectors in x. |
| ind | a factor indicating from which vector in x the observation originated. |

Author(s)

Douglas Bates

See Also

[lm](#), [reshape](#)

Examples

```
require(stats)
formula(PlantGrowth)      # check the default formula
pg <- unstack(PlantGrowth) # unstack according to this formula
pg
stack(pg)                  # now put it back together
stack(pg, select = -ctrl)  # omitting one vector
```

str

*Compactly Display the Structure of an Arbitrary R Object***Description**

Compactly display the internal **structure** of an **R** object, a diagnostic function and an alternative to [summary](#) (and to some extent, [dput](#)). Ideally, only one line for each ‘basic’ structure is displayed. It is especially well suited to compactly display the (abbreviated) contents of (possibly nested) lists. The idea is to give reasonable output for **any** R object. It calls [args](#) for (non-primitive) function objects.

`strOptions()` is a convenience function for setting [options](#)(`str = .`), see the examples.

Usage

```
str(object, ...)

## S3 method for class 'data.frame'
str(object, ...)

## Default S3 method:
str(object, max.level = NA,
     vec.len = str0$vec.len, digits.d = str0$digits.d,
     nchar.max = 128, give.attr = TRUE,
     drop.deparse.attr = str0$drop.deparse.attr,
     give.head = TRUE, give.length = give.head,
     width = getOption("width"), nest.lev = 0,
     indent.str = paste(rep.int(" ", max(0, nest.lev + 1)),
                       collapse = ".."),
     comp.str = "$ ", no.list = FALSE, envir = baseenv(),
     strict.width = str0$strict.width,
     formatNum = str0$formatNum, list.len = str0$list.len,
     deparse.lines = str0$deparse.lines, ...)

strOptions(strict.width = "no", digits.d = 3, vec.len = 4,
           list.len = 99, deparse.lines = NULL,
           drop.deparse.attr = TRUE,
           formatNum = function(x, ...)
             format(x, trim = TRUE, drop0trailing = TRUE, ...))
```

Arguments

| | |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | any R object about which you want to have some information. |
| <code>max.level</code> | maximal level of nesting which is applied for displaying nested structures, e.g., a list containing sub lists. Default NA: Display all nesting levels. |
| <code>vec.len</code> | numeric (≥ 0) indicating how many ‘first few’ elements are displayed of each vector. The number is multiplied by different factors (from .5 to 3) depending |

| | |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| | on the kind of vector. Defaults to the <code>vec.len</code> component of option "str" (see options) which defaults to 4. |
| <code>digits.d</code> | number of digits for numerical components (as for print). Defaults to the <code>digits.d</code> component of option "str" which defaults to 3. |
| <code>nchar.max</code> | maximal number of characters to show for character strings. Longer strings are truncated, see longch example below. |
| <code>give.attr</code> | logical; if TRUE (default), show attributes as sub structures. |
| <code>drop.deparse.attr</code> | logical; if TRUE (default), deparse (<code>control = control</code>) will not have "showAttributes" in <i>control</i> . Used to be hard coded to FALSE and hence can be set via <code>strOptions()</code> for back compatibility. |
| <code>give.length</code> | logical; if TRUE (default), indicate length (as <code>[1:...]</code>). |
| <code>give.head</code> | logical; if TRUE (default), give (possibly abbreviated) mode/class and length (as <code>type[1:...]</code>). |
| <code>width</code> | the page width to be used. The default is the currently active options ("width"); note that this has only a weak effect, unless <code>strict.width</code> is not "no". |
| <code>nest.lev</code> | current nesting level in the recursive calls to <code>str</code> . |
| <code>indent.str</code> | the indentation string to use. |
| <code>comp.str</code> | string to be used for separating list components. |
| <code>no.list</code> | logical; if true, no 'list of ...' nor the class are printed. |
| <code>envir</code> | the environment to be used for <i>promise</i> (see delayedAssign) objects only. |
| <code>strict.width</code> | string indicating if the width argument's specification should be followed strictly, one of the values <code>c("no", "cut", "wrap")</code> , which can be abbreviated. Defaults to the <code>strict.width</code> component of option "str" (see options) which defaults to "no" for back compatibility reasons; "wrap" uses strwrap (<code>*</code> , <code>width = width</code>) whereas "cut" cuts directly to width. Note that a small <code>vec.length</code> may be better than setting <code>strict.width = "wrap"</code> . |
| <code>formatNum</code> | a function such as format for formatting numeric vectors. It defaults to the <code>formatNum</code> component of option "str", see "Usage" of <code>strOptions()</code> above, which is almost back compatible to R <= 2.7.x, however, using formatC may be slightly better. |
| <code>list.len</code> | numeric; maximum number of list elements to display within a level. |
| <code>deparse.lines</code> | numeric or NULL as by default, determining the <code>nlines</code> argument to deparse () when object is a call . When NULL, the <code>nchar.max</code> and <code>width</code> arguments are used to determine a smart default. |
| <code>...</code> | potential further arguments (required for Method/Generic reasons). |

Value

`str` does not return anything, for efficiency reasons. The obvious side effect is output to the terminal.

Note

See the extensive annotated ‘Examples’ below.

The default method tries to “work always”, but needs to make some assumptions for the case when object has a `class` but no own `str()` method which is *the typical* case: There it relies on `"["` and `"[["` subsetting methods to be compatible with `length()`. When this is not the case, or when `is.list(object)` is TRUE, but `length(object)` differs from `length(unclass(object))` it treats it as “irregular” and reports the contents of `unclass(object)` as “hidden list”.

Author(s)

Martin Maechler <maechler@stat.math.ethz.ch> since 1990.

fit <- mle(ll)
str(fit)
```

strcapture

Capture String Tokens into a data.frame

Description

Given a character vector and a regular expression containing capture expressions, `strcapture` will extract the captured tokens into a tabular data structure, such as a `data.frame`, the type and structure of which is specified by a prototype object. The assumption is that the same number of tokens are captured from every input string.

Usage

```
strcapture(pattern, x, proto, perl = FALSE, useBytes = FALSE)
```

Arguments

| | |
|----------------|---------------------------------------------------------------|
| pattern | The regular expression with the capture expressions. |
| x | A character vector in which to capture the tokens. |
| proto | A data.frame or S4 object that behaves like one. See details. |
| perl, useBytes | Arguments passed to regexec . |

Details

The proto argument is typically a data.frame, with a column corresponding to each capture expression, in order. The captured character vector is coerced to the type of the column, and the column names are carried over to the return value. Any data in the prototype are ignored. See the examples.

Value

A tabular data structure of the same type as proto, so typically a data.frame, containing a column for each capture expression. The column types and names are inherited from proto. Cases in x that do not match pattern have NA in every column.

See Also

[regexec](#) and [regmatches](#) for related low-level utilities.

Examples

```
x <- "chr1:1-1000"
pattern <- "(.?):([[:digit:]]+)-([[:digit:]]+)"
proto <- data.frame(chr=character(), start=integer(), end=integer())
strcapture(pattern, x, proto)
```

summaryRprof

Summarise Output of R Sampling Profiler

Description

Summarise the output of the [Rprof](#) function to show the amount of time used by different R functions.

Usage

```
summaryRprof(filename = "Rprof.out", chunksize = 5000,
             memory = c("none", "both", "tseries", "stats"),
             lines = c("hide", "show", "both"),
             index = 2, diff = TRUE, exclude = NULL,
             basenames = 1)
```

Arguments

| | |
|-----------|-------------------------------------------------------------------------------------|
| filename | Name of a file produced by Rprof(). |
| chunksize | Number of lines to read at a time. |
| memory | Summaries for memory information. See ‘Memory profiling’ below. Can be abbreviated. |
| lines | Summaries for line information. See ‘Line profiling’ below. Can be abbreviated. |
| index | How to summarize the stack trace for memory information. See ‘Details’ below. |
| diff | If TRUE memory summaries use change in memory rather than current memory. |
| exclude | Functions to exclude when summarizing the stack trace for memory summaries. |
| basenames | Number of components of the path to filenames to display. |

Details

This function provides the analysis code for [Rprof](#) files used by R CMD Rprof.

As the profiling output file could be larger than available memory, it is read in blocks of chunksize lines. Increasing chunksize will make the function run faster if sufficient memory is available.

Value

If memory = "none" and lines = "hide", a list with components

| | |
|-----------------|-------------------------------------------------|
| by.self | A data frame of timings sorted by ‘self’ time. |
| by.total | A data frame of timings sorted by ‘total’ time. |
| sample.interval | The sampling interval. |
| sampling.time | Total time of profiling run. |

The first two components have columns ‘self.time’, ‘self.pct’, ‘total.time’ and ‘total.pct’, the times in seconds and percentages of the total time spent executing code in that function and code in that function or called from that function, respectively.

If lines = "show", an additional component is added to the list:

| | |
|---------|----------------------------------------------------|
| by.line | A data frame of timings sorted by source location. |
|---------|----------------------------------------------------|

If memory = "both" the same list but with memory consumption in Mb in addition to the timings.

If memory = "tseries" a data frame giving memory statistics over time. Memory usage is in bytes.

If memory = "stats" a [by](#) object giving memory statistics by function. Memory usage is in bytes.

If no events were recorded, a zero-row data frame is returned.

Memory profiling

Options other than `memory = "none"` apply only to files produced by `Rprof(memory.profiling = TRUE)`.

When called with `memory.profiling = TRUE`, the profiler writes information on three aspects of memory use: vector memory in small blocks on the R heap, vector memory in large blocks (from `malloc`), memory in nodes on the R heap. It also records the number of calls to the internal function `duplicate` in the time interval. `duplicate` is called by C code when arguments need to be copied. Note that the profiler does not track which function actually allocated the memory.

With `memory = "both"` the change in total memory (truncated at zero) is reported in addition to timing data.

With `memory = "tseries"` or `memory = "stats"` the `index` argument specifies how to summarize the stack trace. A positive number specifies that many calls from the bottom of the stack; a negative number specifies the number of calls from the top of the stack. With `memory = "tseries"` the `index` is used to construct labels and may be a vector to give multiple sets of labels. With `memory = "stats"` the `index` must be a single number and specifies how to aggregate the data to the maximum and average of the memory statistics. With both `memory = "tseries"` and `memory = "stats"` the argument `diff = TRUE` asks for summaries of the increase in memory use over the sampling interval and `diff = FALSE` asks for the memory use at the end of the interval.

Line profiling

If the code being run has source reference information retained (via `keep.source = TRUE` in `source` or `KeepSource = TRUE` in a package ‘DESCRIPTION’ file or some other way), then information about the origin of lines is recorded during profiling. By default this is not displayed, but the `lines` parameter can enable the display.

If `lines = "show"`, line locations will be used in preference to the usual function name information, and the results will be displayed ordered by location in addition to the other orderings.

If `lines = "both"`, line locations will be mixed with function names in a combined display.

Examples

```
## Not run:
## Rprof() is not available on all platforms
Rprof(tmp <- tempfile())
example(glm)
Rprof()
summaryRprof(tmp)
unlink(tmp)
```

```
## End(Not run)
```

Sweave

Automatic Generation of Reports

Description

Sweave provides a flexible framework for mixing text and R/S code for automatic report generation. The basic idea is to replace the code with its output, such that the final document only contains the text and the output of the statistical analysis: however, the source code can also be included.

Usage

```
Sweave(file, driver = RweaveLatex(),
        syntax = getOption("SweaveSyntax"), encoding = "", ...)

Stangle(file, driver = Rtangle(),
        syntax = getOption("SweaveSyntax"), encoding = "", ...)
```

Arguments

| | |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| file | Path to Sweave source file. Note that this can be supplied without the extension, but the function will only proceed if there is exactly one Sweave file in the directory whose basename matches file. |
| driver | the actual workhorse, (a function returning) a named list of five functions; for details, see Section 5 of the ‘Sweave User Manual’ available as vignette("Sweave") . |
| syntax | NULL or an object of class "SweaveSyntax" or a character string with its name. See the section ‘Syntax Definition’. |
| encoding | The default encoding to assume for file. |
| ... | further arguments passed to the driver’s setup function. See RweaveLatexSetup and RtangleSetup , respectively, for the arguments of the default drivers. |

Details

An Sweave source file contains both text in a markup language (like \LaTeX) and R (or S) code. The code gets replaced by its output (text or graphs) in the final markup file. This allows a report to be re-generated if the input data change and documents the code to reproduce the analysis in the same file that also produces the report.

Sweave combines the documentation and code chunks (or their output) into a single document. Stangle extracts only the code from the Sweave file creating an R source file that can be run using [source](#). (Code inside `\Sexpr{}` statements is ignored by Stangle.)

Stangle is just a wrapper to Sweave specifying a different default driver. Alternative drivers can be used and are provided by various contributed packages.

Environment variable `SWEAVE_OPTIONS` can be used to override the initial options set by the driver: it should be a comma-separated set of `key=value` items, as would be used in a `'\SweaveOpts'` statement in a document.

If the encoding is unspecified (the default), *non-ASCII* source files must contain a line of the form

```
\usepackage[foo]{inputenc}
```

(where `'foo'` is typically `'latin1'`, `'latin2'`, `'utf8'` or `'cp1252'` or `'cp1250'`) or a comment line

```
%\SweaveUTF8
```

to declare UTF-8 input (the default encoding assumed by pdfTeX since 2018), or they will give an error. Re-encoding can be turned off completely with argument `encoding = "bytes"`.

Syntax Definition

Sweave allows a flexible syntax framework for marking documentation and text chunks. The default is a noweb-style syntax, as alternative a L^AT_EX-style syntax can be used. (See the user manual for further details.)

If `syntax = NULL` (the default) then the available syntax objects are consulted in turn, and selected if their extension component matches (as a regexp) the file name. Objects `SweaveSyntaxNoweb` (with `extension = "[.]rsRSnw$"`) and `SweaveSyntaxLatex` (with `extension = "[.]rsRS$"`) are supplied, but users or packages can supply others with names matching the pattern `SweaveSyntax.*`.

|----------------|------------------------------|
| SweaveSyntConv | <i>Convert Sweave Syntax</i> |
|----------------|------------------------------|

Description

This function converts the syntax of files in [Sweave](#) format to another Sweave syntax definition.

Usage

```
SweaveSyntConv(file, syntax, output = NULL)
```

Arguments

| | |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| file | Name of Sweave source file. |
| syntax | An object of class SweaveSyntax or a character string with its name giving the target syntax to which the file is converted. |
| output | Name of output file, default is to remove the extension from the input file and to add the default extension of the target syntax. Any directory names in file are also removed such that the output is created in the current working directory. |

## and run it through Sweave
Sweave("Sweave-test-1.Stex")
```

| | |
|-----|----------------------|
| tar | Create a Tar Archive |
|-----|----------------------|

Description

Create a tar archive.

Usage

```
tar(tarfile, files = NULL,
    compression = c("none", "gzip", "bzip2", "xz"),
    compression_level = 6, tar = Sys.getenv("tar"),
    extra_flags = "")
```

Arguments

| | |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| tarfile | The pathname of the tar file: tilde expansion (see path.expand) will be performed. Alternatively, a connection that can be used for binary writes. |
| files | A character vector of filepaths to be archived: the default is to archive all files under the current directory. |
| compression | character string giving the type of compression to be used (default none). Can be abbreviated. |
| compression_level | integer: the level of compression. Only used for the internal method. |
| tar | character string: the path to the command to be used. If the command itself contains spaces it needs to be quoted (e.g., by shQuote) – but argument tar may also contain flags separated from the command by spaces. |
| extra_flags | Any extra flags for an external tar. |

Details

This is either a wrapper for a tar command or uses an internal implementation in R. The latter is used if `tarfile` is a connection or if the argument `tar` is `"internal"` or `""` (the 'factory-fresh' default). Note that whereas Unix-alike versions of R set the environment variable `TAR`, its value is not the default for this function.

Argument `extra_flags` is passed to an external tar and so is platform-dependent. Possibly useful values include `'-h'` (follow symbolic links, also `'-L'` on some platforms), `'--acls'`, `'--exclude-backups'`, `'--exclude-vcs'` (and similar) and on Windows `'--force-local'` (so drives can be included in filepaths). Rtools 4 and earlier included a tar which used `'--force-local'`, but Rtools 4.2 includes original GNU tar, which does not use it by default.

A convenient and robust way to set options for GNU tar is via environment variable `TAR_OPTIONS`. Appending `'--force-local'` to `TAR` does not work with GNU tar due to restrictions on how some options can be mixed. The tar available on Windows 10 (libarchive's `bsdtar`) supports drive letters by default. It does not support the `'--force-local'`, but ignores `TAR_OPTIONS`.

For GNU tar, `'--format=ustar'` forces a more portable format. (The default is set at compilation and will be shown at the end of the output from `tar --help`: for version 1.30 'out-of-the-box' it is `'--format=gnu'`, but the manual says the intention is to change to `'--format=posix'` which is the same as pax – it was never part of the POSIX standard for tar and should not be used.) For libarchive's `bsdtar`, `'--format=ustar'` is more portable than the default.

One issue which can cause an external command to fail is a command line too long for the system shell: as from R 3.5.0 this is worked around if the external command is detected to be GNU tar or libarchive tar (aka `bsdtar`).

Note that `files = '.'` will usually not work with an external tar as that would expand the list of files after `tarfile` is created. (It does work with the default internal method.)

Value

The return code from `system` or 0 for the internal version, invisibly.

Portability

The 'tar' format no longer has an agreed standard! 'Unix Standard Tar' was part of POSIX 1003.1:1998 but has been removed in favour of pax, and in any case many common implementations diverged from the former standard.

Many R platforms use a version of GNU tar, but the behaviour seems to be changed with each version. macOS >= 10.6, FreeBSD and Windows 10 use `bsdtar` from the libarchive project (but for macOS often a quite-old version), and commercial Unixes will have their own versions. `bsdtar` is available for many other platforms: macOS up to at least 10.9 had GNU tar as `gnutar` and other platforms, e.g. Solaris, have it as `gtar`: on a Unix-alike configure will try `gnutar` and `gtar` before tar.

Known problems arise from

- The handling of file paths of more than 100 bytes. These were unsupported in early versions of tar, and supported in one way by POSIX tar and in another by GNU tar and yet another by the POSIX pax command which recent tar programs often support. The internal implementation warns on paths of more than 100 bytes, uses the 'ustar' way from the 1998 POSIX

standard which supports up to 256 bytes (depending on the path: in particular the final component is limited to 100 bytes) if possible, otherwise the GNU way (which is widely supported, including by [untar](#)).

Most formats do not record the encoding of file paths.

- (File) links. `tar` was developed on an OS that used hard links, and physical files that were referred to more than once in the list of files to be included were included only once, the remaining instances being added as links. Later a means to include symbolic links was added. The internal implementation supports symbolic links (on OSes that support them), only. Of course, the question arises as to how links should be unpacked on OSes that do not support them: for regular files file copies can be used.

Names of links in the ‘ustar’ format are restricted to 100 bytes. There is an GNU extension for arbitrarily long link names, but `bsdtar` ignores it. The internal method uses the GNU extension, with a warning.

- Header fields, in particular the padding to be used when fields are not full or not used. POSIX did define the correct behaviour but commonly used implementations did (and still do) not comply.
- File sizes. The ‘ustar’ format is restricted to 8GB per (uncompressed) file.

For portability, avoid file paths of more than 100 bytes and all links (especially hard links and symbolic links to directories).

The internal implementation writes only the blocks of 512 bytes required (including trailing blocks of NULs), unlike GNU `tar` which by default pads with ‘nul’ to a multiple of 20 blocks (10KB). Implementations which pad differ on whether the block padding should occur before or after compression (or both): padding was designed for improved performance on physical tape drives.

The ‘ustar’ format records file modification times to a resolution of 1 second: on file systems with higher resolution it is conventional to discard fractional seconds.

Compression

When an external `tar` command is used, compressing the tar archive requires that `tar` supports the ‘-z’, ‘-j’ or ‘-J’ flag, and may require the appropriate command (`gzip`, `bzip2` or `xz`) to be available. For GNU `tar`, further compression programs can be specified by e.g. `extra_flags = "-I lz4"`. Some versions of `bsdtar` accept options such as ‘--lz4’, ‘--lzop’ and ‘--lrzip’ or an external compressor *via* ‘--use-compress-program lz4’: these could be supplied in `extra_flags`.

NetBSD prior to 8.0 used flag ‘--xz’ rather than ‘-J’, so this should be used *via* `extra_flags = "--xz"` rather than `compression = "xz"`. The commands from OpenBSD and the Heirloom Toolchest are not documented to support `xz`.

The `tar` programs in commercial Unixen such as AIX and Solaris do not support compression.

Note

For users of macOS. Apple’s file systems have a legacy concept of ‘resource forks’ dating from classic Mac OS and rarely used nowadays. Apple’s version of `tar` stores these as separate files in the tarball with names prefixed by ‘._’, and unpacks such files into resource forks (if possible): other ways of unpacking (including [untar](#) in R) unpack them as separate files.

When argument `tar` is set to the command `tar` on macOS, environment variable `COPYFILE_DISABLE=1` is set, which for the system version of `tar` prevents these separate files being included in the tarball.

[untar](#).

toLatex

Converting R Objects to BibTeX or LaTeX

Description

These methods convert R objects to character vectors with BibTeX or LaTeX markup.

Usage

```
toBibtex(object, ...)
toLatex(object, ...)
## S3 method for class 'Bibtex'
print(x, prefix = "", ...)
## S3 method for class 'Latex'
print(x, prefix = "", ...)
```

Arguments

| | |
|--------|----------------------------------------------------------------------------------------------------------------------|
| object | object of a class for which a toBibtex or toLatex method exists. |
| x | object of class "Bibtex" or "Latex". |
| prefix | a character string which is printed at the beginning of each line, mostly used to insert whitespace for indentation. |
| ... | in the print methods, passed to writeLines . |

Details

Objects of class "Bibtex" or "Latex" are simply character vectors where each element holds one line of the corresponding BibTeX or LaTeX file.

See Also

[citEntry](#) and [sessionInfo](#) for examples

| | |
|----------------|--------------------------|
| txtProgressBar | <i>Text Progress Bar</i> |
|----------------|--------------------------|

Description

Text progress bar in the R console.

Usage

```
txtProgressBar(min = 0, max = 1, initial = 0, char = "=",
               width = NA, title, label, style = 1, file = "")

getTxtProgressBar(pb)
setTxtProgressBar(pb, value, title = NULL, label = NULL)
## S3 method for class 'txtProgressBar'
close(con, ...)
```

Arguments

| | |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| min, max | (finite) numeric values for the extremes of the progress bar. Must have min < max. |
| initial, value | initial or new value for the progress bar. See ‘Details’ for what happens with invalid values. |
| char | the character (or character string) to form the progress bar. Must have non-zero display width. |
| width | the width of the progress bar, as a multiple of the width of char. If NA, the default, the number of characters is that which fits into <code>getOption("width")</code> . |
| style | the ‘style’ of the bar – see ‘Details’. |
| file | an open connection object or "" which indicates the console: <code>stderr()</code> might be useful here. |
| pb, con | an object of class "txtProgressBar". |
| title, label | ignored, for compatibility with other progress bars. |
| ... | for consistency with the generic. |

Details

`txtProgressBar` will display a progress bar on the R console (or a connection) via a text representation.

`setTxtProgressBar` will update the value. Missing (NA) and out-of-range values of value will be (silently) ignored. (Such values of initial cause the progress bar not to be displayed until a valid value is set.)

The progress bar should be closed when finished with: this outputs the final newline character.

`style = 1` and `style = 2` just shows a line of char. They differ in that `style = 2` redraws the line each time, which is useful if other code might be writing to the R console. `style = 3` marks the end of the range by ‘|’ and gives a percentage to the right of the bar.

Value

For txtProgressBar an object of class "txtProgressBar".

For getTxtProgressBar and setTxtProgressBar, a length-one numeric vector giving the previous value (invisibly for setTxtProgressBar).

Note

Using style 2 or 3 or reducing the value with style = 1 uses '\r' to return to the left margin – the interpretation of carriage return is up to the terminal or console in which R is running, and this is liable to produce ugly output on a connection other than a terminal, including when stdout() is redirected to a file.

See Also

[winProgressBar](#) (Windows only), [tkProgressBar](#) (Unix-alike platforms).

Examples

```
# slow
testit <- function(x = sort(runif(20)), ...)
{
  pb <- txtProgressBar(...)
  for(i in c(0, x, 1)) {Sys.sleep(0.5); setTxtProgressBar(pb, i)}
  Sys.sleep(1)
  close(pb)
}
testit()
testit(runif(10))
testit(style = 3)
testit(char=' \u27a4')
```

type.convert

Convert Data to Appropriate Type

Description

Convert a data object to logical, integer, numeric, complex, character or factor as appropriate.

Usage

```
type.convert(x, ...)
## Default S3 method:
type.convert(x, na.strings = "NA", as.is, dec = ".",
             numerals = c("allow.loss", "warn.loss", "no.loss"),
             tryLogical = TRUE, ...)
## S3 method for class 'data.frame'
type.convert(x, ...)
## S3 method for class 'list'
type.convert(x, ...)
```

Arguments

| | |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code> | a vector, matrix, array, data frame, or list. |
| <code>na.strings</code> | a vector of strings which are to be interpreted as NA values. Blank fields are also considered to be missing values in logical, integer, numeric or complex vectors. |
| <code>as.is</code> | whether to store strings as plain character. When false, convert character vectors to factors. See ‘Details’. |
| <code>dec</code> | the character to be assumed for decimal points. |
| <code>numerals</code> | string indicating how to convert numbers whose conversion to double precision would lose accuracy, typically when <code>x</code> has more digits than can be stored in a double . Can be abbreviated. Possible values are <code>numerals = "allow.loss"</code> , default : the conversion happens with some accuracy loss. <code>numerals = "warn.loss"</code> : a warning about accuracy loss is signalled and the conversion happens as with <code>numerals = "allow.loss"</code> . <code>numerals = "no.loss"</code> : <code>x</code> is <i>not</i> converted to a number, but to a factor or character, depending on <code>as.is</code> . |
| <code>tryLogical</code> | a logical determining if vectors consisting entirely of F, T, FALSE, TRUE and <code>na.strings</code> should be converted to logical ; true, by default. |
| <code>...</code> | arguments to be passed to or from methods. |

Details

This helper function is used by [read.table](#). When the data object `x` is a data frame or list, the function is called recursively for each column or list element.

Given a vector, the function attempts to convert it to logical, integer, numeric or complex, and when additionally `as.is = FALSE` (no longer the default!), converts a character vector to [factor](#). The first type that can accept all the non-missing values is chosen.

Vectors which are entirely missing values are converted to logical, since NA is primarily logical.

If `tryLogical` is true as by default, vectors containing just F, T, FALSE, TRUE and values from `na.strings` are converted to logical. This may be surprising in a context where you have many character columns with e.g., 1-letter strings and you happen to get one with only "F". In such cases `tryLogical = FALSE` is recommended. Vectors containing optional whitespace followed by decimal constants representable as R integers or values from `na.strings` are converted to integer. Other vectors containing optional whitespace followed by other decimal or hexadecimal constants (see [NumericConstants](#)), or NaN, Inf or infinity (ignoring case) or values from `na.strings` are converted to numeric. Where converting inputs to numeric or complex would result in loss of accuracy they can optionally be returned as strings or (for `as.is = FALSE`) factors.

Since this is a helper function, the caller should always pass an appropriate value of `as.is`.

Value

An object like `x` but using another storage mode when appropriate.

Author(s)

R Core, with a contribution by Arni Magnusson

See Also

[read.table](#), [class](#), [storage.mode](#).

Examples

```
## Numeric to integer
class(rivers)
x <- type.convert(rivers, as.is = TRUE)
class(x)

## Convert many columns
auto <- type.convert(mtcars, as.is = TRUE)
str(mtcars)
str(auto)

## Convert matrix
phones <- type.convert(WorldPhones, as.is = TRUE)
storage.mode(WorldPhones)
storage.mode(phones)

## Factor or character
chr <- c("A", "B", "B", "A")
ch2 <- c("F", "F", "NA", "F")
(fac <- factor(chr))
type.convert(chr, as.is = FALSE) # -> factor
type.convert(fac, as.is = FALSE) # -> factor
type.convert(chr, as.is = TRUE)  # -> character
type.convert(fac, as.is = TRUE)  # -> character
type.convert(ch2, as.is = TRUE)  # -> logical
type.convert(ch2, as.is = TRUE, tryLogical=FALSE) # -> character
```

untar

Extract or List Tar Archives

Description

Extract files from or list the contents of a tar archive.

Usage

```
untar(tarfile, files = NULL, list = FALSE, exdir = ".",
      compressed = NA, extras = NULL, verbose = FALSE,
      restore_times = TRUE,
      support_old_tars = Sys.getenv("R_SUPPORT_OLD_TARS", FALSE),
      tar = Sys.getenv("TAR"))
```

Arguments

| | |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| tarfile | The pathname of the tar file: tilde expansion (see path.expand) will be performed. Alternatively, a connection that can be used for binary reads. For a <i>compressed</i> tarfile, and if a connection is to be used, that should be created by gzfile(.) (or gzcon(.) which currently only works for "gzip", whereas gzfile() works for all compressions available in tar()). |
| files | A character vector of recorded filepaths to be extracted: the default is to extract all files. |
| list | If TRUE, list the files (the equivalent of <code>tar -tf</code>). Otherwise extract the files (the equivalent of <code>tar -xf</code>). |
| exdir | The directory to extract files to (the equivalent of <code>tar -C</code>). It will be created if necessary. |
| compressed | (Deprecated in favour of auto-detection, used only for an external tar command.) Logical or character string. Values "gzip", "bzip2" and "xz" select that form of compression (and may be abbreviated to the first letter). TRUE indicates gzip compression, FALSE no known compression, and NA (the default) indicates that the type is to be inferred from the file header. The external command may ignore the selected compression type but detect a type automagically. |
| extras | NULL or a character string: further command-line flags such as '-p' to be passed to an external tar program. |
| verbose | logical: if true echo the command used for an external tar program. |
| restore_times | logical. If true (default) restore file modification times. If false, the equivalent of the '-m' flag. Times in tarballs are supposed to be in UTC, but tarballs have been submitted to CRAN with times in the future or far past: this argument allows such times to be discarded. Note that file times in a tarball are stored with a resolution of 1 second, and can only be restored to the resolution supported by the file system (which on a FAT system is 2 seconds). |
| support_old_tars | logical. If false (the default), the external tar command is assumed to be able handle compressed tarfiles and if <code>compressed</code> does not specify it, to automagically detect the type of compression. (The major implementations have done so since 2009; for GNU tar since version 1.22.) If true, the R code calls an appropriate decompressor and pipes the output to tar, for <code>compressed = NA</code> examining the tarfile header to determine the type of compression. |
| tar | character string: the path to the command to be used or "internal". If the command itself contains spaces it needs to be quoted – but tar can also contain flags separated from the command by spaces. |

Details

This is either a wrapper for a tar command or for an internal implementation written in R. The latter is used if `tarfile` is a connection or if the argument `tar` is "internal" or "" (except on Windows, when `tar.exe` is tried first).

Unless otherwise stated three types of compression of the tar file are supported: gzip, bzip2 and xz.

What options are supported will depend on the tar implementation used: the "internal" one is intended to provide support for most in a platform-independent way.

GNU tar: Modern GNU tar versions support compressed archives and since 1.15 are able to detect the type of compression automatically: version 1.22 added support for xz compression.

On a Unix-alike, configure will set environment variable TAR, preferring GNU tar if found.

bsdtar: macOS 10.6 and later (and FreeBSD and some other OSes) have a tar from the libarchive project which detects all three forms of compression automatically (even if undocumented in macOS).

NetBSD: It is undocumented if NetBSD's tar can detect compression automatically: for versions before 8 the flag for xz compression was '--xz' not '-J'. So support_old_tars = TRUE is recommended (or use bsdtar if installed).

OpenBSD: OpenBSD's tar does not detect compression automatically. It has no support for xz beyond reporting that the file is xz-compressed. So support_old_tars = TRUE is recommended.

Heirloom Toolchest: This tar does automatically detect gzip and bzip2 compression (undocumented) but has no support for xz compression.

Older support: Environment variable R_GZIPCMD gives the command to decompress gzip files, and R_BZIPCMD for bzip2 files. (On Unix-alikes these are set at installation if found.) xz is used if available: if not decompression is expected to fail.

Arguments compressed, extras and verbose are only used when an external tar is used.

Some external tar commands will detect some of lrzip, lzma, lz4, lzop and zstd compression in addition to gzip, bzip2 and xz. (For some external tar commands, compressed tarfiles can only be read if the appropriate utility program is available.) For GNU tar, further (de)compression programs can be specified by e.g. extras = "-I lz4". For bsdtar this could be extras = "--use-compress-program lz4". Most commands will detect (the nowadays rarely seen) '.tar.Z' archives compressed by compress.

The internal implementation restores symbolic links as links on a Unix-alike, and as file copies on Windows (which works only for existing files, not for directories), and hard links as links. If the linking operation fails (as it may on a FAT file system), a file copy is tried. Since it uses [gzfile](#) to read a file it can handle files compressed by any of the methods that function can handle: at least compress, gzip, bzip2 and xz compression, and some types of lzma compression. It does not guard against restoring absolute file paths, as some tar implementations do. It will create the parent directories for directories or files in the archive if necessary. It handles the USTAR/POSIX, GNU and pax ways of handling file paths of more than 100 bytes, and the GNU way of handling link targets of more than 100 bytes.

You may see warnings from the internal implementation such as

```
unsupported entry type 'x'
```

This often indicates an invalid archive: entry types "A-Z" are allowed as extensions, but other types are reserved. The only thing you can do with such an archive is to find a tar program that handles it, and look carefully at the resulting files. There may also be the warning

using pax extended headers

This indicates that additional information may have been discarded, such as ACLs, encodings

The former standards only supported ASCII filenames (indeed, only alphanumeric plus period, underscore and hyphen). `untar` makes no attempt to map filenames to those acceptable on the current system, and treats the filenames in the archive as applicable without any re-encoding in the current locale.

The internal implementation does not special-case ‘resource forks’ in macOS: that system’s `tar` command does. This may lead to unexpected files with names with prefix ‘. _’.

Value

If `list = TRUE`, a character vector of (relative or absolute) paths of files contained in the tar archive. Otherwise the return code from `system` with an external `tar` or `0L`, invisibly.

See Also

[tar](#), [unzip](#).

| | |
|-------|-------------------------------------|
| unzip | <i>Extract or List Zip Archives</i> |
|-------|-------------------------------------|

Description

Extract files from or list a zip archive.

Usage

```
unzip(zipfile, files = NULL, list = FALSE, overwrite = TRUE,
      junkpaths = FALSE, exdir = ".", unzip = "internal",
      setTimes = FALSE)
```

Arguments

| | |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| zipfile | The pathname of the zip file: tilde expansion (see path.expand) will be performed. |
| files | A character vector of recorded filepaths to be extracted: the default is to extract all files. |
| list | If TRUE, list the files and extract none. The equivalent of <code>unzip -l</code> . |
| overwrite | If TRUE, overwrite existing files (the equivalent of <code>unzip -o</code>), otherwise ignore such files (the equivalent of <code>unzip -n</code>). |
| junkpaths | If TRUE, use only the basename of the stored filepath when extracting. The equivalent of <code>unzip -j</code> . |
| exdir | The directory to extract files to (the equivalent of <code>unzip -d</code>). It will be created if necessary. |

| | |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| unzip | The method to be used. An alternative is to use <code>getOption("unzip")</code> , which on a Unix-alike may be set to the path to a unzip program. |
| setTimes | logical. For the internal method only, should the file times be set based on the times in the zip file? (NB: this applies to included files, not to directories.) |

Value

If `list = TRUE`, a data frame with columns `Name` (character) `Length` (the size of the uncompressed file, numeric) and `Date` (of class `"POSIXct"`).

Otherwise for the `"internal"` method, a character vector of the filepaths extracted to, invisibly.

Note

The default internal method is a minimal implementation, principally designed for Windows' users to be able to unpack Windows binary packages without external software. It does not (for example) support Unicode filenames as introduced in zip 3.0: for that use `unzip = "unzip"` with unzip 6.00 or later. It does have some support for bzip2 compression and > 2GB zip files (but not >= 4GB files pre-compression contained in a zip file: like many builds of unzip it may truncate these, in R's case with a warning if possible).

If `unzip` specifies a program, the format of the dates listed with `list = TRUE` is unknown (on Windows it can even depend on the current locale) and the return values could be NA or expressed in the wrong time zone or misinterpreted (the latter being far less likely as from unzip 6.00).

File times in zip files are stored in the style of MS-DOS, as local times to an accuracy of 2 seconds. This is not very useful when transferring zip files between machines (even across continents), so we chose not to restore them by default.

Source

The internal C code uses `zlib` and is in particular based on the contributed 'minizip' application in the `zlib` sources (from <https://zlib.net/>) by Gilles Vollant.

See Also

[unz](#) to read a single component from a zip file.

[zip](#) for packing, i.e., the "inverse" of `unzip()`; further [untar](#) and [tar](#), the corresponding pair for (un)packing tar archives ("tarballs") such as R source packages.

update.packages

Compare Installed Packages with CRAN-like Repositories

Description

`old.packages` indicates packages which have a (suitable) later version on the repositories whereas `update.packages` offers to download and install such packages.

`new.packages` looks for (suitable) packages on the repositories that are not already installed, and optionally offers them for installation.

Usage

```

update.packages(lib.loc = NULL, repos = getOption("repos"),
               contriburl = contrib.url(repos, type),
               method, instlib = NULL,
               ask = TRUE, available = NULL,
               oldPkgs = NULL, ..., checkBuilt = FALSE,
               type = getOption("pkgType"))

old.packages(lib.loc = NULL, repos = getOption("repos"),
            contriburl = contrib.url(repos, type),
            instPkgs = installed.packages(lib.loc = lib.loc, ...),
            method, available = NULL, checkBuilt = FALSE, ...,
            type = getOption("pkgType"))

new.packages(lib.loc = NULL, repos = getOption("repos"),
            contriburl = contrib.url(repos, type),
            instPkgs = installed.packages(lib.loc = lib.loc, ...),
            method, available = NULL, ask = FALSE, ...,
            type = getOption("pkgType"))

```

Arguments

| | |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| lib.loc | character vector describing the location of R library trees to search through (and update packages therein), or NULL for all known trees (see .libPaths). |
| repos | character vector, the base URL(s) of the repositories to use, e.g., the URL of a CRAN mirror such as "https://cloud.r-project.org". |
| contriburl | URL(s) of the contrib sections of the repositories. Use this argument if your repository is incomplete. Overrides argument repos. Incompatible with type = "both". |
| method | Download method, see download.file . Unused if a non-NULL available is supplied. |
| instlib | character string giving the library directory where to install the packages. |
| ask | logical indicating whether to ask the user to select packages before they are downloaded and installed, or the character string "graphics", which brings up a widget to allow the user to (de)select from the list of packages which could be updated. The latter value only works on systems with a GUI version of select.list , and is otherwise equivalent to ask = TRUE. ask does not control questions asked before installing packages from source via type = "both" (see option "install.packages.compile.from.source"). |
| available | an object as returned by available.packages listing packages available at the repositories, or NULL which makes an internal call to available.packages. Incompatible with type = "both". |
| checkBuilt | If TRUE, a package built under an earlier major.minor version of R (e.g., 3.4) is considered to be 'old'. |
| oldPkgs | if specified as non-NULL, update.packages() only considers these packages for updating. This may be a character vector of package names or a matrix as returned by old.packages. |

| | |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| instPkgs | by default all installed packages, installed.packages (lib.loc = lib.loc). A subset can be specified; currently this must be in the same (character matrix) format as returned by installed.packages (). |
| ... | Arguments such as <code>destdir</code> and dependencies to be passed to install.packages and <code>ignore_repo_cache</code> , <code>max_repo_cache_age</code> and <code>noCache</code> to available.packages or installed.packages . |
| type | character, indicating the type of package to download and install. See install.packages . |

Details

`old.packages` compares the information from [available.packages](#) with that from `instPkgs` (computed by [installed.packages](#) by default) and reports installed packages that have newer versions on the repositories or, if `checkBuilt = TRUE`, that were built under an earlier minor version of R (for example built under 3.3.x when running R 3.4.0). (For binary package types there is no check that the version on the repository was built under the current minor version of R, but it is advertised as being suitable for this version.)

`new.packages` does the same comparison but reports uninstalled packages that are available at the repositories. If `ask != FALSE` it asks which packages should be installed in the first element of `lib.loc`.

The main function of the set is `update.packages`. First a list of all packages found in `lib.loc` is created and compared with those available at the repositories. If `ask = TRUE` (the default) packages with a newer version are reported and for each one the user can specify if it should be updated. If so the packages are downloaded from the repositories and installed in the respective library path (or `instlib` if specified).

For how the list of suitable available packages is determined see [available.packages](#). `available = NULL` make a call to `available.packages(contriburl = contriburl, method = method)` and hence by default filters on R version, OS type and removes duplicates.

Value

`update.packages` returns NULL invisibly.

For `old.packages`, NULL or a matrix with one row per package, row names the package names and column names "Package", "LibPath", "Installed" (the version), "Built" (the version built under), "ReposVer" and "Repository".

For `new.packages` a character vector of package names, *after* any selected *via* `ask` have been installed.

Warning

Take care when using dependencies (passed to [install.packages](#)) with `update.packages`, for it is unclear where new dependencies should be installed. The current implementation will only allow it if all the packages to be updated are in a single library, when that library will be used.

| | |
|---------|----------------|
| upgrade | <i>Upgrade</i> |
|---------|----------------|

Description

Upgrade objects.

Usage

```
upgrade(object, ...)
```

Arguments

| | |
|---------------------|----------------------------------------------------|
| <code>object</code> | an R object. |
| <code>...</code> | further arguments passed to or from other methods. |

Details

This is a generic function, with a method for "[packageStatus](#)" objects.

| | |
|----------|---------------------------|
| url.show | <i>Display a Text URL</i> |
|----------|---------------------------|

Description

Extension of [file.show](#) to display text files from a remote server.

Usage

```
url.show(url, title = url, file = tempfile(),
         delete.file = TRUE, method, ...)
```

Arguments

| | |
|--------------------------|---------------------------------------------------------|
| <code>url</code> | The URL to read from. |
| <code>title</code> | Title for the browser. |
| <code>file</code> | File to copy to. |
| <code>delete.file</code> | Delete the file afterwards? |
| <code>method</code> | File transfer method: see download.file |
| <code>...</code> | Arguments to pass to file.show . |

Note

Since this is for text files, it will convert to CRLF line endings on Windows.

See Also

[url](#), [file.show](#), [download.file](#)

Examples

```
## Not run: url.show("https://www.stats.ox.ac.uk/pub/datasets/csb/ch3a.txt")
```

| | |
|-----------|----------------------------------------|
| URLencode | <i>Encode or Decode (partial) URLs</i> |
|-----------|----------------------------------------|

Description

Functions to percent-encode or decode characters in URLs.

Usage

```
URLencode(URL, reserved = FALSE, repeated = FALSE)
URLdecode(URL)
```

Arguments

| | |
|-----------------------|-------------------------------------------------------------------|
| <code>URL</code> | a character vector. |
| <code>reserved</code> | logical: should ‘reserved’ characters be encoded? See ‘Details’. |
| <code>repeated</code> | logical: should apparently already-encoded URLs be encoded again? |

Details

Characters in a URL other than the English alphanumeric characters and ‘- _ . ~’ should be encoded as % plus a two-digit hexadecimal representation, and any single-byte character can be so encoded. (Multi-byte characters are encoded byte-by-byte.) The standard refers to this as ‘percent-encoding’. In addition, ‘! \$ & ' () * + , ; = : / ? @ # []’ are reserved characters, and should be encoded unless used in their reserved sense, which is scheme specific. The default in `URLencode` is to leave them alone, which is appropriate for ‘file://’ URLs, but probably not for ‘http://’ ones. An ‘apparently already-encoded URL’ is one containing %xx for two hexadecimal digits.

Value

A character vector.

References

Internet STD 66 (formerly RFC 3986), <https://www.rfc-editor.org/info/std66>

Examples

```
(y <- URLencode("a url with spaces and / and @"))
URLdecode(y)
(y <- URLencode("a url with spaces and / and @", reserved = TRUE))
URLdecode(y)

URLdecode(z <- "ab%20cd")
c(URLencode(z), URLencode(z, repeated = TRUE)) # first is usually wanted

## both functions support character vectors of length > 1
y <- URLdecode(URLencode(c("url with space", "another one")))
```

utils-deprecated

*Deprecated Functions in Package **utils***

Description

(Currently none)

These functions are provided for compatibility with older versions of R only, and may be defunct as soon as of the next release.

See Also

[Deprecated](#), [Defunct](#)

View

Invoke a Data Viewer

Description

Invoke a spreadsheet-style data viewer on a matrix-like R object.

Usage

```
View(x, title)
```

Arguments

| | |
|--------------------|----------------------------------------------------------------------------------------------|
| <code>x</code> | an R object which can be coerced to a data frame with non-zero numbers of rows and columns. |
| <code>title</code> | title for viewer window. Defaults to name of <code>x</code> prefixed by <code>Data:</code> . |

Details

Object `x` is coerced (if possible) to a data frame, then columns are converted to character using [format.data.frame](#). The object is then viewed in a spreadsheet-like data viewer, a read-only version of [data.entry](#).

If there are row names on the data frame that are not `1:nrow`, they are displayed in a separate first column called `row.names`.

Objects with zero columns or zero rows are not accepted.

On Unix-alikes, the array of cells can be navigated by the cursor keys and Home, End, Page Up and Page Down (where supported by X11) as well as Enter and Tab.

On Windows, the array of cells can be navigated *via* the scrollbars and by the cursor keys, Home, End, Page Up and Page Down.

On Windows, the initial size of the data viewer window is taken from the default dimensions of a pager (see [Rconsole](#)), but adjusted downwards to show a whole number of rows and columns.

Value

Invisible NULL. The functions puts up a window and returns immediately: the window can be closed via its controls or menus.

See Also

[edit.data.frame](#), [data.entry](#).

vignette

View, List or Get R Source of Package Vignettes

Description

View a specified package vignette, or list the available ones; display it rendered in a viewer, and get or edit its R source file.

Usage

```
vignette(topic, package = NULL, lib.loc = NULL, all = TRUE)
```

```
## S3 method for class 'vignette'
print(x, ...)
## S3 method for class 'vignette'
edit(name, ...)
```

Arguments

| | |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>topic</code> | a character string giving the (base) name of the vignette to view. If omitted, all vignettes from all installed packages are listed. |
| <code>package</code> | a character vector with the names of packages to search through, or <code>NULL</code> in which ‘all’ packages (as defined by argument <code>all</code>) are searched. |
| <code>lib.loc</code> | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. |
| <code>all</code> | logical; if <code>TRUE</code> search all available packages in the library trees specified by <code>lib.loc</code> , and if <code>FALSE</code> , search only attached packages. |
| <code>x, name</code> | object of class <code>vignette</code> . |
| <code>...</code> | ignored by the print method, passed on to <code>file.edit</code> by the edit method. |

Details

Function `vignette` returns an object of the same class, the print method opens a viewer for it.

On Unix-alikes, the program specified by the `pdfviewer` option is used for viewing PDF versions of vignettes.

If several vignettes have PDF/HTML versions with base name identical to `topic`, the first one found is used.

If no topics are given, all available vignettes are listed. The corresponding information is returned in an object of class `"packageIQR"`.

See Also

`browseVignettes` for an HTML-based vignette browser; `RShowDoc("basename", package = "pkgname")` displays a “rendered” vignette (pdf or html).

Examples

```
## List vignettes from all *attached* packages
vignette(all = FALSE)

## List vignettes from all *installed* packages (can take a long time!):
vignette(all = TRUE)

## The grid intro vignette -- open it
## Not run: vignette("grid") # calling print()
## The same (conditional on existence of the vignette).
## Note that 'package = *' is much faster in the case of many installed packages:
if(!is.null(v1 <- vignette("grid", package="grid"))) {
  ## Not run: v1 # calling print(.)
  str(v1)
  ## Now let us have a closer look at the code

  ## Not run: edit(v1) # e.g., to send lines ...
```

```

}# if( has vignette "installed")
## A package can have more than one vignette (package grid has several):
vignette(package = "grid")
if(interactive()) {
  ## vignette("rotated")
  ## The same, but without searching for it:
  vignette("rotated", package = "grid")
}

```

warnErrList

Collect and Summarize Errors From List

Description

Collect errors (class "error", typically from [tryCatch](#)) from a list `x` into a "summary warning", by default produce a [warning](#) and keep that message as "warningMsg" attribute.

Usage

```
warnErrList(x, warn = TRUE, errValue = NULL)
```

Arguments

| | |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code> | a list , typically from applying models to a list of data (sub)sets, e.g., using tryCatch (*, error = identity). |
| <code>warn</code> | logical indicating if warning () should be called. |
| <code>errValue</code> | the value with which errors should be replaced. |

Value

a [list](#) of the same length and names as the `x` argument, with the error components replaced by `errValue`, `NULL` by default, and summarized in the "warningMsg" attribute.

See Also

The `warnErrList()` utility has been used in [lmList\(\)](#) and [nlslList\(\)](#) in recommended package [nlme](#) forever.

Examples

```

## Regression for each Chick:
ChWtgrps <- split(ChickWeight, ChickWeight[, "Chick"])
sapply(ChWtgrps, nrow)# typically 12 obs.
nlis1 <- lapply(ChWtgrps, function(DAT) tryCatch(error = identity,
  lm(weight ~ (Time + I(Time^2)) * Diet, data = DAT)))
nl1 <- warnErrList(nlis1) #-> warning :
## 50 times the same error (as Diet has only one level in each group)
stopifnot(sapply(nl1, is.null)) ## all errors --> all replaced by NULL
nlis2 <- lapply(ChWtgrps, function(DAT) tryCatch(error = identity,

```

```

      lm(weight ~ Time + I(Time^2), data = DAT)))
n12 <- warnErrList(nlis2)
stopifnot(identical(n12, nlis2)) # because there was *no* error at all
nlis3 <- lapply(ChWtgrps, function(DAT) tryCatch(error = identity,
      lm(weight ~ poly(Time, 3), data = DAT)))
n13 <- warnErrList(nlis3) # 1 error caught:
stopifnot(inherits(nlis3[[1]], "error")
      , identical(n13[-1], nlis3[-1])
      , is.null(n13[[1]]))
)

## With different error messages
if(requireNamespace("nlme")) { # almost always, as it is recommended
  data(Soybean, package="nlme")
  attr(Soybean, "formula") #-> weight ~ Time | Plot => split by "Plot":
  L <- lapply(split(Soybean, Soybean[, "Plot"]),
      function(DD) tryCatch(error = identity,
        nls(weight ~ SSlogis(Time, Asym, xmid, scal), data = DD)))
  Lw <- warnErrList(L)
} # if <nlme>

```

winDialog

Dialog Boxes under Windows

Description

On MS Windows only, put up a dialog box to communicate with the user. There are various types, either for the user to select from a set of buttons or to edit a string.

Usage

```
winDialog(type = c("ok", "okcancel", "yesno", "yesnocancel"),
  message)
```

```
winDialogString(message, default)
```

Arguments

| | |
|---------|------------------------------------------------------------------------------------------------------|
| type | character. The type of dialog box. It will have the buttons implied by its name. |
| message | character. The information field of the dialog box. Limited to 255 chars (by Windows, checked by R). |
| default | character. The default string. |

Value

For winDialog a character string giving the name of the button pressed (in capitals) or NULL (invisibly) if the user had no choice.

For winDialogString a string giving the contents of the text box when Ok was pressed, or NULL if Cancel was pressed.

Note

The standard keyboard accelerators work with these dialog boxes: where appropriate Return accepts the default action, Esc cancels and the underlined initial letter (Y or N) can be used.

These functions are only available on Windows.

See Also

[winMenuAdd](#)

[file.choose](#) to select a file

package `windlgs` in the package source distribution for ways to program dialogs in C in the GraphApp toolkit.

Examples

```
## Not run: winDialog("yesno", "Is it OK to delete file blah")
```

winextras

Get Windows Version

Description

Get the self-reported Microsoft Windows version number.

Usage

```
win.version()
```

Details

`win.version` is an auxiliary function for [sessionInfo](#) and [bug.report](#).

Value

A character string describing the version of Windows reported to be in use.

Note

This function is only available on Microsoft Windows.

The result is based on the Windows `GetVersionEx` API function. It is not known how to detect a version of Windows before it is released, and hence the textual information returned by R may identify an older version than installed. The build number is more reliable. When running R in compatibility mode, the reported version including the build number is the compatibility version, not the installed version.

Examples

```
if(.Platform$OS.type == "windows")  
  print(win.version())
```

winMenus

*User Menus under MS Windows (RGui)***Description**

Enables users to add, delete and program menus for the Rgui in MS Windows.

Usage

```
winMenuAdd(menuname)
winMenuAddItem(menuname, itemname, action)
winMenuDel(menuname)
winMenuDelItem(menuname, itemname)
winMenuNames()
winMenuItems(menuname)
```

Arguments

| | |
|----------|------------------------------------------------------------------------------------------------|
| menuname | a character string naming a menu. |
| itemname | a character string naming a menu item on an existing menu. |
| action | a character string describing the action when that menu is selected, or "enable" or "disable". |

Details

User menus are added to the right of existing menus, and items are added at the bottom of the menu. By default the action character string is treated as R input, being echoed on the command line and parsed and executed as usual.

If the menuname parameter of winMenuAddItem does not already exist, it will be created automatically.

Normally new submenus and menu items are added to the main console menu. They may be added elsewhere using the following special names:

```
$ConsoleMain The console menu (the default)
$ConsolePopup The console popup menu
$Graph<n>Main The menu for graphics window <n>
$Graph<n>Popup The popup menu for graphics window <n>
```

Specifying an existing item in winMenuAddItem enables the action to be changed.

Submenus can be specified by separating the elements in menuname by slashes: as a consequence menu names may not contain slashes.

If the action is specified as "none" no action is taken: this can be useful to reserve items for future expansion.

The function winMenuNames can be used to find out what menus have been created by the user and returns a vector of the existing menu names.

The winMenuItems function will take the name of a menu and return the items that exist in that menu. The return value is a named vector where the names correspond to the names of the items and the values of the vector are the corresponding actions.

The winMenuDel function will delete a menu and all of its items and submenus. winMenuDelItem just deletes one menu item.

The total path to an item (menu string plus item string) cannot exceed 1000 bytes, and the menu string cannot exceed 500 bytes.

Value

NULL, invisibly. If an error occurs, an informative error message will be given.

Note

These functions are only available on Windows and only when using the Rgui, hence not in ESS nor RStudio.

See Also

[winDialog](#)

Examples

```
## Not run:
winMenuAdd("Testit")
winMenuAddItem("Testit", "one", "aaaa")
winMenuAddItem("Testit", "two", "bbbb")
winMenuAdd("Testit/extras")
winMenuAddItem("Testit", "-", "")
winMenuAddItem("Testit", "two", "disable")
winMenuAddItem("Testit", "three", "cccc")
winMenuAddItem("Testit/extras", "one more", "ddd")
winMenuAddItem("Testit/extras", "and another", "eee")
winMenuAdd("$ConsolePopup/Testit")
winMenuAddItem("$ConsolePopup/Testit", "six", "fff")
winMenuNames()
winMenuItems("Testit")

## End(Not run)
```

Description

Put up a Windows progress bar widget, update and access it.

Usage

```
winProgressBar(title = "R progress bar", label = "",
               min = 0, max = 1, initial = 0, width = 300)

getWinProgressBar(pb)
setWinProgressBar(pb, value, title = NULL, label = NULL)
## S3 method for class 'winProgressBar'
close(con, ...)
```

Arguments

| | |
|----------------|-----------------------------------------------------------------------------------------------|
| title, label | character strings, giving the window title and the label on the dialog box respectively. |
| min, max | (finite) numeric values for the extremes of the progress bar. |
| initial, value | initial or new value for the progress bar. |
| width | the width of the progress bar in pixels: the dialog box will be 40 pixels wider (plus frame). |
| pb, con | an object of class "winProgressBar". |
| ... | for consistency with the generic. |

Details

winProgressBar will display a progress bar centred on the screen. Space will be allocated for the label only if it is non-empty.

setWinProgressbar will update the value and for non-NULL values, the title and label (provided there was one when the widget was created). Missing (NA) and out-of-range values of value will be (silently) ignored.

The progress bar should be closed when finished with, but it will be garbage-collected once no R object refers to it.

Value

For winProgressBar an object of class "winProgressBar".

For getWinProgressBar and setWinProgressBar, a length-one numeric vector giving the previous value (invisibly for setWinProgressBar).

Note

These functions are only available on Windows.

write.table

*Data Output***Description**

write.table prints its required argument `x` (after converting it to a data frame if it is not one nor a matrix) to a file or [connection](#).

Usage

```
write.table(x, file = "", append = FALSE, quote = TRUE, sep = " ",
            eol = "\n", na = "NA", dec = ".", row.names = TRUE,
            col.names = TRUE, qmethod = c("escape", "double"),
            fileEncoding = "")

write.csv(...)
write.csv2(...)
```

Arguments

| | |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code> | the object to be written, preferably a matrix or data frame. If not, it is attempted to coerce <code>x</code> to a data frame. |
| <code>file</code> | either a character string naming a file or a connection open for writing. "" indicates output to the console. |
| <code>append</code> | logical. Only relevant if <code>file</code> is a character string. If TRUE, the output is appended to the file. If FALSE, any existing file of the name is destroyed. |
| <code>quote</code> | a logical value (TRUE or FALSE) or a numeric vector. If TRUE, any character or factor columns will be surrounded by double quotes. If a numeric vector, its elements are taken as the indices of columns to quote. In both cases, row and column names are quoted if they are written. If FALSE, nothing is quoted. |
| <code>sep</code> | the field separator string. Values within each row of <code>x</code> are separated by this string. |
| <code>eol</code> | the character(s) to print at the end of each line (row). For example, <code>eol = "\r\n"</code> will produce Windows' line endings on a Unix-alike OS, and <code>eol = "\r"</code> will produce files as expected by Excel:mac 2004. |
| <code>na</code> | the string to use for missing values in the data. |
| <code>dec</code> | the string to use for decimal points in numeric or complex columns: must be a single character. |
| <code>row.names</code> | either a logical value indicating whether the row names of <code>x</code> are to be written along with <code>x</code> , or a character vector of row names to be written. |
| <code>col.names</code> | either a logical value indicating whether the column names of <code>x</code> are to be written along with <code>x</code> , or a character vector of column names to be written. See the section on 'CSV files' for the meaning of <code>col.names = NA</code> . |

| | |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| qmethod | a character string specifying how to deal with embedded double quote characters when quoting strings. Must be one of "escape" (default for write.table), in which case the quote character is escaped in C style by a backslash, or "double" (default for write.csv and write.csv2), in which case it is doubled. You can specify just the initial letter. |
| fileEncoding | character string: if non-empty declares the encoding to be used on a file (not a connection) so the character data can be re-encoded as they are written. See file . |
| ... | arguments to write.table: append, col.names, sep, dec and qmethod cannot be altered. |

Details

If the table has no columns the rownames will be written only if row.names = TRUE, and *vice versa*.

Real and complex numbers are written to the maximal possible precision.

If a data frame has matrix-like columns these will be converted to multiple columns in the result (via [as.matrix](#)) and so a character col.names or a numeric quote should refer to the columns in the result, not the input. Such matrix-like columns are unquoted by default.

Any columns in a data frame which are lists or have a class (e.g., dates) will be converted by the appropriate as.character method: such columns are unquoted by default. On the other hand, any class information for a matrix is discarded and non-atomic (e.g., list) matrices are coerced to character.

Only columns which have been converted to character will be quoted if specified by quote.

The dec argument only applies to columns that are not subject to conversion to character because they have a class or are part of a matrix-like column (or matrix), in particular to columns protected by I(). Use [options](#)("OutDec") to control such conversions.

In almost all cases the conversion of numeric quantities is governed by the option "scipen" (see [options](#)), but with the internal equivalent of digits = 15. For finer control, use [format](#) to make a character matrix/data frame, and call write.table on that.

These functions check for a user interrupt every 1000 lines of output.

If file is a non-open connection, an attempt is made to open it and then close it after use.

To write a Unix-style file on Windows, use a binary connection e.g. file = file("filename", "wb").

CSV files

By default there is no column name for a column of row names. If col.names = NA and row.names = TRUE a blank column name is added, which is the convention used for CSV files to be read by spreadsheets. Note that such CSV files can be read in R by

```
read.csv(file = "<filename>", row.names = 1)
```

write.csv and write.csv2 provide convenience wrappers for writing CSV files. They set sep and dec (see below), qmethod = "double", and col.names to NA if row.names = TRUE (the default) and to TRUE otherwise.

write.csv uses "." for the decimal point and a comma for the separator.

write.csv2 uses a comma for the decimal point and a semicolon for the separator, the Excel convention for CSV files in some Western European locales.

These wrappers are deliberately inflexible: they are designed to ensure that the correct conventions are used to write a valid file. Attempts to change append, col.names, sep, dec or qmethod are ignored, with a warning.

CSV files do not record an encoding, and this causes problems if they are not ASCII for many other applications. Windows Excel 2007/10 will open files (e.g., by the file association mechanism) correctly if they are ASCII or UTF-16 (use fileEncoding = "UTF-16LE") or perhaps in the current Windows codepage (e.g., "CP1252"), but the 'Text Import Wizard' (from the 'Data' tab) allows far more choice of encodings. Excel:mac 2004/8 can *import* only 'Macintosh' (which seems to mean Mac Roman), 'Windows' (perhaps Latin-1) and 'PC-8' files. OpenOffice 3.x asks for the character set when opening the file.

There is an IETF RFC4180 (<https://www.rfc-editor.org/rfc/rfc4180>) for CSV files, which mandates comma as the separator and CRLF line endings. write.csv writes compliant files on Windows: use eol = "\r\n" on other platforms.

Note

write.table can be slow for data frames with large numbers (hundreds or more) of columns: this is inevitable as each column could be of a different class and so must be handled separately. If they are all of the same class, consider using a matrix instead.

See Also

The 'R Data Import/Export' manual.

[read.table](#), [write](#).

[write.matrix](#) in package **MASS**.

Examples

```
x <- data.frame(a = I("a \" quote"), b = pi)
tf <- tempfile(fileext = ".csv")

## To write a CSV file for input to Excel one might use
write.table(x, file = tf, sep = ",", col.names = NA,
            qmethod = "double")
file.show(tf)
## and to read this file back into R one needs
read.table(tf, header = TRUE, sep = ",", row.names = 1)
## NB: you do need to specify a separator if qmethod = "double".

### Alternatively
write.csv(x, file = tf)
read.csv(tf, row.names = 1)
## or without row names
write.csv(x, file = tf, row.names = FALSE)
read.csv(tf)
```

```
## Not run:
## To write a file in Mac Roman for simple use in Mac Excel 2004/8
write.csv(x, file = "foo.csv", fileEncoding = "macroman")
## or for Windows Excel 2007/10
write.csv(x, file = "foo.csv", fileEncoding = "UTF-16LE")

## End(Not run)
```

zip

Create Zip Archives

Description

A wrapper for an external zip command to create zip archives.

Usage

```
zip(zipfile, files, flags = "-r9X", extras = "",
    zip = Sys.getenv("R_ZIPCMD", "zip"))
```

Arguments

| | |
|---------|-----------------------------------------------------------------------------------------------------|
| zipfile | The pathname of the zip file: tilde expansion (see path.expand) will be performed. |
| files | A character vector of recorded filepaths to be included. |
| flags | A character string of flags to be passed to the command: see ‘Details’. |
| extras | An optional character vector: see ‘Details’. |
| zip | A character string specifying the external command to be used. |

Details

On a Unix-alike, the default for zip will use the value of R_ZIPCMD, whose default is set in ‘etc/Renviron’ to the zip command found during configuration. On Windows, the default relies on a zip program (for example that from Rtools) being in the path.

The default for flags is that appropriate for zipping up a directory tree in a portable way: see the system-specific help for the zip command for other possibilities.

Argument extras can be used to specify -x or -i followed by a list of filepaths to exclude or include. Since extras will be treated as if passed to [system](#), if the filepaths contain spaces they must be quoted e.g. by [shQuote](#).

Value

The status value returned by the external command, invisibly.

See Also

[unzip](#), [unz](#); further, [tar](#) and [untar](#) for (un)packing tar archives.
